# Chapter 1

**Dopaminergic regulation of action  
potential timing**

Information processing along sensorimotor pathways requires integration of bottom-up sensory input from the periphery with the top-down computations of the brain. From a sensory processing perspective, adaptive (plausibly neuromodulatory) control of spike timing is of particular interest as rapid propagation of information via ascending sensory pathways requires stimulus-coupled spiking that is correlated across neurons. Here we review the role of dopamine in controlling neuronal excitability and propose that dopaminergic modulation of voltage-gated sodium channels might be an efficient, yet unexplored/unidentified, mechanism for top-down control of spike timing during bottom-up propagation of sensory information. Mechanistic understanding of the contextual control over sensory representations will help to determine how neural representations of the world are shaped by behavioral and perceptual priors.

Dopamine is central to many neural processes including the modulation of the reward system, motor control, pleasure and higher cognitive functions<sup>1-4</sup>. Dysfunctions in the dopaminergic pathways are associated with aggression and violence<sup>5</sup>, schizophrenia<sup>6,7</sup>, Parkinson's Disease (PD)<sup>8,9</sup>, addiction<sup>10-13</sup>, anxiety disorders<sup>14</sup> and Attention Deficit Hyperactivity Disorder (ADHD)<sup>7,15</sup>.

There are two classes of dopamine receptors that includes five subtypes: D1-like receptors are composed of the subfamily of D1 and D5 receptors (D1R, D5R), and the D2-like receptors that include the D2R, D3R and D4R<sup>16,17</sup>. Dopamine receptors are also found as D1-D2 heteromers<sup>18</sup>, and as heteromers with various other G-protein coupled receptors (GPCR)<sup>19,20</sup>. Furthermore, dopamine can bind to Trace Amine Associated Receptor 1 (TAAR1) which modulates presynaptic dopaminergic transmission<sup>21,22</sup>. Considering that dopaminergic neurons might release dopamine extra-synaptically (including somato-dendritically<sup>23,24</sup>) and might release neurotransmitters other than dopamine, such as glutamate, serotonin, endocannabinoids, neurotensin and cholecystokinin<sup>25,26</sup>, it is not surprising that dopamine contributes to numerous behaviorally relevant computations throughout the brain, including state dependent changes in neuronal communication<sup>27,28</sup>.

State-dependent computations are critical for an animal to adapt its behavior to the ever-changing environment and to create appropriate motor actions. Although the role of dopamine in controlling motor behavior is well documented (see e.g.<sup>29,30</sup>), dopaminergic modulation of sensory processing is yet to be mechanistically understood<sup>31-33</sup>. Here we provide a critical review of the literature on the dopaminergic regulation of neural activity, experience-dependent plasticity and network activity, focusing on sensorimotor circuits. We argue that one key, albeit not yet explored, mechanism with which dopamine could shape sensory representations of the world is the modulation of voltage-gated sodium channels to control action potential timing. Understanding the mechanisms of top/down regulation of sensory representations might help to differentiate the mechanisms of perceptual and experience-dependent plasticity in the sensory systems<sup>34</sup>, while providing a mechanistic insight into how adaptive sensorimotor computations emerge in a context dependent manner.

### Dopaminergic control of neuronal communication

In the rodent brain, dopaminergic projections mature postnatally, targeting virtually the entire brain, including ascending and descending sensorimotor circuits<sup>31</sup>. Depending on the receptor localization, the neuronal classes they are expressed in, and the dopaminergic receptors types that are (in)activated, dopamine release may result in excitation or inhibition. For example, in the medial prefrontal cortex (mPFC), dopamine release inhibits glutamatergic signaling<sup>35</sup>; in the entorhinal cortex, phasic dopamine release after reward leads to the suppression

of excitatory synaptic responses via the D2-like receptors <sup>36</sup>. Although dopamine readily suppresses action potential backpropagation, if D2 receptors are inactivated simultaneously, the dendritic T-type calcium channels can be recruited, resulting in increased dendritic excitability and calcium inflow during dopaminergic transmission <sup>37</sup>.

Dopamine contributes to sensory information processing. In the olfactory bulb, dopamine reduces spontaneous excitatory synaptic events by reducing evoked presynaptic calcium currents, suggesting that dopamine inhibits neurotransmission via presynaptic mechanisms in the mitral/tufted cells <sup>38</sup>. In the striatum, D1 neurons respond to ipsilateral somatosensory stimulation with earlier latency and higher firing rates than D2 neurons, which argues that D1 and D2 may have complementary functions for sensory stimulus processing <sup>39</sup>; D1 neurons might act as a comparator for the sensory information on the ipsilateral and contralateral whiskers <sup>33</sup>, while D2 neurons seem to act as integrators <sup>39</sup>. Interestingly, midbrain dopaminergic neurons regulate their spike rate based on the sensory features of the expected rewarded stimulus <sup>32</sup>. Given that these neurons send projections to the extragranular layers of the somatosensory cortex <sup>31</sup>, where cross-columnar topographic sensory integration takes place <sup>40,41</sup>, dopamine might also shape the topographical (map) representations of the sensory organs, contributing to integration of sensory information across whiskers <sup>42</sup> already in the primary somatosensory cortex.

One of the best studied functional roles for dopamine is its contribution to motor control (see e.g. <sup>43–45</sup> for recent reviews). D2R activation modulates firing rates both in Parkinsonian and non-Parkinsonian rats, possibly through the activation of the GABAergic transmission <sup>46</sup>. In the rodent brain stem, suppression of dopaminergic signaling results in the inhibition of oscillatory input in the pedunculopontine nucleus originating from the basal ganglia. This inhibition could help to explain the role of dopamine in the development of motor phenotypes in PD <sup>47</sup>. In PD patients, levodopa application enhances the long range, cross hemispheric temporal correlations in local field potentials, improving neuronal communication in the basal ganglia <sup>48</sup>. The dopaminergic depletion in the nigrostriatal neurons increases coherence in the motor cortex, but decreases the local field potential power in the medial prefrontal cortex and subthalamic nucleus (STN), which might help regulate the communication between motor and cognitive networks <sup>49</sup>. Taken together, dopamine can control neuronal excitability and communication across sensory, motor, cognitive and executive networks in the brain, and altered dopaminergic transmission is relevant to the development of various neuropathological phenotypes.

### Intracellular mechanisms for dopaminergic modulation of neuronal excitability

As a neuromodulatory neurotransmitter dopamine's action is not the direct regulation of the membrane potential. It depends on the functional state of neurons <sup>4</sup>. Dopamine receptors are associated with guanosine triphosphate-binding proteins (G-proteins) and mediate their effects in the postsynaptic neurons by controlling surface receptors via (de)phosphorylation, or by modulating downstream enzymatic cascades and transcription factors (Figure 1).

**Figure 1. Major intracellular signaling cascades modulated by dopamine.** DA receptors are coupled to G-proteins, differentially controlling the (de)phosphorylation of ion channels. **D1R activation** starts a signaling cascade with the activation of AC through Gs. AC increases cAMP concentration and activates PKA, which phosphorylates PPP1R1B. PPP1R1B is an integrator of synaptic input, indirectly increasing Na<sup>+</sup> channels phosphorylation via dephosphorylation of PP-1. PKA directly regulates the phosphorylation of voltage-dependent Na<sup>+</sup> and Ca<sup>2+</sup> channels. D1R activation also inhibits K<sup>+</sup> channels through Gq. **D2R activation** inhibits AC through Gi, thus reducing intracellular levels of cAMP. Activation of PP2A and  $\beta$ Arr1 indirectly modulates the phosphorylation of glutamatergic AMPA and NMDA receptors, via dephosphorylation of GSK-3 and CamKII. PLC activation, through Gq, contributes to the phosphorylation of K<sup>+</sup> channels and balances the intracellular Ca<sup>2+</sup>, through IP3, CaM and calcineurin. The last dephosphorylates PPP1R1B, indirectly contributing to the dephosphorylation of Na<sup>+</sup> channels. PLC interacts with DAG in the membrane, activating PKC, modulating Na<sup>+</sup> channels, and increasing intracellular Ca<sup>2+</sup>. The latter leads to the activation of MAPK and the transcription factor C-Fos. Abbreviations: *Neurotransmitter*: DA: dopamine; *Ions*: K<sup>+</sup>: potassium; Ca<sup>2+</sup>: calcium; Na<sup>+</sup>: sodium; *Ion channels*: GIRK: G-protein coupled inwardly rectifying potassium channel; VGCC: voltage-gated calcium channel; Na<sub>v</sub>: voltage-gated sodium channel; *Ligand gated channels*:

D1R: D1-like receptor; D2R: D2-like receptor; AMPAR:  $\alpha$ -amino-3-hydroxy-5-methyl-4- isoxazolepropionic acid receptor; NMDAR: *N*-methyl-D-aspartate receptor; *G-protein receptor subunits*: Gq: subunit q; Gs: subunit alpha s; Gi: subunit alpha i; *Biochemical regulators (enzymes and intracellular proteins)*: AC: adenylyl cyclase; cAMP: cyclic adenosine monophosphate; PKA: protein kinase A; PPP1R1B: protein phosphatase 1 regulatory subunit 1B; CREB: cAMP response element-binding protein; PP-1: protein phosphatase 1; PLC: phospholipase C; DAG: diacylglycerol; IP3: inositol triphosphate; PKC: protein kinase C; MAPK: mitogen-activated protein kinase; PP2A: protein phosphatase 2;  $\beta$ ArrII:  $\beta$  arrestin II; GSK-3: glycogen synthase kinase 3; CaM: calmodulin; CaMKII:  $\text{Ca}^{2+}$ /calmodulin-dependent protein kinase II.

Dopamine controls ion channel dynamics via (de)phosphorylation. Dopaminergic activation of the D1R increases cAMP concentration leading to PKA activation (see Figure 1). Because PKA is an enzyme that phosphorylates a large variety of downstream protein targets, it mediates both short- and long-term dynamics of the cellular responses to neuromodulation. For example, PKA is bound to sodium channels via 15 kDa cAMP-dependent protein kinase-anchoring protein (AKAP-15)<sup>50,51</sup> and phosphorylates voltage-gated  $\text{Na}^+$  ( $\text{Na}_v$ ) channels in four sites<sup>52–54</sup>. The D1R activation reduces the  $\text{Na}^+$  peak transient without changing its kinetics or voltage-dependence in neocortical neurons<sup>52</sup>. This dopamine-mediated “gain modulation” of sodium conductance is conserved throughout evolution, as it is also found in amphibians<sup>55</sup>. D1 receptor activation can modulate ionic flow across the membrane also via phosphorylation of the protein phosphatase 1 regulatory subunit 1B (PPP1R1B, also known as DARPP-32, dopamine and cAMP regulated neuronal phosphoprotein)<sup>56</sup>. PPP1R1B acts as an integrator of synaptic input in dopamine neurons<sup>57</sup>. Glutamate induces dephosphorylation of PPP1R1B and this mechanism of phosphorylation/dephosphorylation of PPP1R1B dynamically and powerfully modulates  $\text{Na}_v$  channels<sup>58</sup>. The control over the spike after-hyperpolarization suggests that dopamine might modulate potassium conductance in postsynaptic neurons (Figure 1): while D1-like receptors mediate the membrane depolarization (through a G protein-coupled  $\text{K}^+$  channel or inwardly rectifying  $\text{K}^+$  channel), the D2-like receptors activation increase the action potential discharge, possibly involving slowly inactivating  $\text{K}^+$  channels (e.g.  $\text{K}_v1$ )<sup>63</sup>.

Dopaminergic regulation of spiking is cell-type specific. In striatal low-threshold interneurons, dopamine increases spike frequency by membrane depolarization upon D1R activation<sup>64</sup>. Dopamine might regulate GABAergic currents in medium spiny neurons (MSNs), as dopamine depletion generates burst spiking of GABAergic interneurons<sup>65</sup>. In the STN, dopaminergic regulation of the inhibitory currents is modulated by T-type calcium currents, which depolarize the membrane potential to the spike threshold, increasing burst firing<sup>66</sup>. Dopaminergic neurons in the midbrain have a slow irregular firing pattern that is generated by a slow depolarization current and by a calcium-activated potassium after-hyperpolarization

current ( $I_{K(Ca)}$ ), the former enabling the membrane potential to reach the spike threshold<sup>67</sup>. The slow depolarization is voltage-dependent and TTX-sensitive, suggesting that early dopaminergic action is mediated through  $Na_v$ ; the spike after-hyperpolarization depends on high-threshold dendritic calcium spikes<sup>68</sup>.

Dopamine controls neuronal excitability through the regulation of action potential generation (see above) as well as through membrane hyperpolarization through inhibition of hyperpolarization-activated, cyclic nucleotide-modulated (HCN) channels. HCN channels are potent regulators of excitability in various cell types in the heart and the brain, including the somatosensory neurons<sup>69</sup>. In olfactory receptor neurons, dopamine suppresses the slowly activated current  $I_h$  through D2R, leading to more hyperpolarized potentials and reduced peak currents, while cAMP activation through D1R depolarizes the  $I_h$ <sup>70,71</sup>. Dopamine enhances  $I_h$  in cortical interneurons in layer 1, involving a cooperative interaction between D1-like and D2-like receptors that also requires GPCR signaling through the G-protein beta-gamma complex<sup>72,73</sup>. Interestingly, D3R-mediated suppression of high frequency spiking does not involve GPCR signaling. Instead, D3R regulate the neuronal excitability via calcium voltage-dependent channels (Cav3) in the axonal initial segment<sup>74</sup>.

The empirical observations covered thus far argue that dopaminergic action on the membrane excitability is mediated through two membrane bound enzymes: AC and PLC. They are differentially recruited by the D1-like and D2-like receptors (Figure 1), regulating the calcium release from the intracellular calcium stores.

Considering the complex dopaminergic action on the postsynaptic excitability, computational modelling might help to reduce the dimensionality and shed light onto the critical biochemical events that lead to neuronal modulation by dopamine. Accordingly, a recent biophysical model of dopaminergic circuits argued that the key mechanism that is responsible for the dopamine-mediated reduction in excitability, is the inhibition of calcium activated potassium channels (SK), which subsequently results in a reduction of the number of open  $Na^+$  channels<sup>75</sup> because of their greater inactivation. Combined with the phosphorylation of  $Na_v$  channels by dopamine<sup>76</sup> (see Figure 1), these mechanisms could potentially control cell excitability and postsynaptic evoked responses. In support of these findings, recordings from the neocortical layer 5 excitatory neurons already showed that dopamine attenuates evoked excitatory postsynaptic potentials (EPSP) as the area and the duration of the EPSP are reduced upon D1R activation through reduction of persistent  $Na^+$  currents ( $I_{NAP}$ )<sup>77</sup>. With multiple  $Na_v$  subunits, e.g.  $Na_v1.1$ ,  $Na_v1.2$  or  $Na_v1.6 \alpha$ , that might give rise to both  $I_{NAP}$  and fast  $Na^+$  currents as a response to dopamine, further research will be required to identify the receptor basis of dopaminergic regulation of the sodium currents.

In summary, although dopamine acts through GPCRs, and dopaminergic receptor

activation does not result in a direct ionic exchange across the membrane, dopamine potently modulates sodium, potassium and calcium conductances in the postsynaptic neurons, gating action potential generation. Because this sustained change in ion channel conductance is a key step in the regulation of synaptic efficacy, dopaminergic control of neuronal excitability might also contribute to bidirectional changes in synaptic plasticity.

### **A modulatory close-loop between dopaminergic and sensorimotor circuits**

Dopaminergic regulation of neuronal, including sensorimotor, excitability (see Section 1) and experience-dependent regulation of dopamine signaling in the somatosensory cortex (see Chapter 4) both argue that there is a modulatory close-loop between dopaminergic transmission and sensory processing. Considering the monosynaptic projections originating from somatosensory- and motor-cortical neurons, and targeting VTA and SNc <sup>78</sup>, this close-loop might have a short latency. Dopamine release from VTA and SNc, in return, could influence with the neural activity throughout the brain (Figure 3), including sensorimotor circuits in brainstem, thalamus and cortex <sup>31</sup>, completing the close-loop.

A common property of close-loop neuronal circuits is that the activity along the circuit could be regulated by both ascending (bottom-up) and descending (top-down) projections. Although there is ample empirical evidence in support of descending dopaminergic control of sensorimotor circuits, contribution of the sensorimotor projections to dopaminergic neurons' spiking is yet to be systematically studied. Just to give a few examples: high frequency VTA stimulation *in vivo* leads to prolonged calcium transients in the secondary motor cortex (in the prefrontal cortex) while low frequency stimulation induces brief (tonic) transients <sup>79</sup>. Increased dopamine availability decreases the excitability of pyramidal tract neurons in the primary motor cortex, where both D1 and D2 receptors expressed <sup>80</sup>. Electrical stimulations in the ventral midbrain dopaminergic neurons leads to short-latency phasic activations in the auditory cortex through D1R-mediated activation <sup>81</sup>. D2R activation via quinpirole reduces stimulus (tone) evoked spiking, and subsequently auditory sensory gating of aversive events <sup>82</sup>. In the olfactory (piriform) cortex of rats, dopamine suppresses excitatory responses after reward via D2R<sup>36</sup>. In the somatosensory cortex, the blockade of D1 and D2R increases sensory evoked potential amplitudes by 107.5% and 82.1%, respectively <sup>83</sup>. Dopaminergic modulation of sensorimotor neuronal activity is not limited to the central nervous system. In the periphery, e.g. adult sensory neurons, dopamine regulates calcium channels in a voltage-(in)dependent manner <sup>84</sup>.

**Figure 2. Regulatory close-loops between dopaminergic and key sensorimotor nuclei.** Symbols in circles depict the physiological role of dopaminergic signaling in controlling neuronal excitability. Experimental evidence on the simplified anatomical circuit includes **PFC** (prefrontal cortex): D1R, but not D2R, activation reduces AP-evoked calcium influx in the dendrites<sup>85</sup>, decreases the spike threshold and first interspike interval in the soma<sup>86</sup>. **GP** (globus pallidus): Dopamine in GP decreases firing rate in the STN and SN<sup>87</sup> which might be mediated through the increased excitability of inhibitory neurons after D2R stimulation<sup>46</sup>; **VB** (ventrobasal thalamus): Selective D1R and D2R activation results in membrane depolarization and increased firing rates<sup>63</sup>; **SN** (substantia nigra): DA in SN increases the firing rate of GP neurons. D2R activation decreases firing via increasing spike threshold in the SN and in the **VTA** (ventral tegmental area)<sup>88–90</sup>; **STN** (subthalamic nucleus): D1R, but not D2R, agonist reduces spontaneous firing while either one increases frequency of bursting<sup>91</sup>; **M1** (Primary motor cortex): Both D1R and D2R activation results in inhibition of pyramidal tract neurons in the motor cortex<sup>80</sup>.

The broad extent of dopaminergic projections indicates a spatial and temporal significance for the dopamine signaling. In the hypothalamus, reward increases dopamine release in the entorhinal cortex phasically, following a D2R-mediated suppression of excitatory postsynaptic responses<sup>36</sup>. In the auditory cortex, dopamine is necessary for controlling the frequency of responses to rhythmic sensory inputs<sup>92</sup>. In the basal ganglia, dopamine increases long range temporal correlations across motor nuclei interfering with the motor communication processing<sup>48</sup>. Dopaminergic loss in the basal ganglia increases the inhibitory oscillatory communication between basal ganglia and PPN (pedunclopontine nucleus)<sup>47</sup>, and increases synchronization between the SN and the motor cortex during ongoing motor activity<sup>93</sup>, showing the relevance of dopamine signaling in bottom-up and top-down temporal and spatial coherence for the brain signaling. Therefore, higher cortical areas seem to modulate motor and sensory circuits throughout the dopaminergic tuning of respectively, the nigrostriatal and the basal-ganglia-thalamocortical network activity.

## Conclusions

Sensory neurons represent the world that surrounds us by varying the rate and timing of their action potentials. Because information from the sensory periphery propagates through feed-forward excitatory projections, and is shaped by inhibitory circuit motives, previous research in sensory cortices focused on the roles of glutamatergic and GABAergic signaling in shaping neural representations.

Sensory neurons, however, integrate information from the sensory periphery with the information (e.g. expectations, memories, emotional states) generated internally, elsewhere in the brain. These top-down projections are mediated through neuromodulatory neurotransmitters which alter postsynaptic signaling through slower G-protein signaling. Here, we reviewed the experimental evidence which argues that one of the cardinal neuromodulatory neurotransmitters, dopamine, could potently and rapidly regulate action potential timing (also see Chapter 5). Given that sensory experience regulates dopaminergic signaling in the primary somatosensory cortex (see Chapter 4) and sensorimotor circuits form a close-loop network with dopaminergic circuits (see Section 3), top-down regulation of action potential timing through dopaminergic modulation might mechanistically help to describe how internal neural representations of the external sensory world are shaped by behavioral and perceptual priors. Therefore, in thesis I addressed the top-down regulation of sensory neuronal excitability using mouse somatosensory (barrel) cortex as a model. The main conclusions are:

- Dopamine suppresses neuronal excitability.
- D1 and D2 receptor mediated control of excitability is mediated through voltage-gated sodium channels and manifested through modulation of the action potential threshold.
- D1 mediated control of excitability is cell-type specific. Upon D1 receptor activation excitatory neuron firing rate is decreased while inhibitory neuronal firing rate is increased.
- Sensory deprivation alters transcription of genes in the dopaminergic signaling pathway in a cortical layer specific manner suggesting that there is a functional close-loop between the dopaminergic signaling and sensory experience.
- Corticosterone controls evoked calcium transients in vitro and sensory representations in vivo, which suggests that top-down modulation of sensory neuron excitability is not specific to dopamine

# Chapter 2

**A databank for intracellular  
electrophysiological mapping of the adult  
somatosensory cortex**

Neurons in the supragranular layers of the somatosensory cortex integrate sensory (bottom-up) and cognitive/perceptual (top-down) information as they orchestrate communication across cortical columns. It has been inferred, based on intracellular recordings from juvenile animals, that supragranular neurons are electrically mature by the fourth postnatal week. However, the dynamics of the neuronal integration in the adulthood is largely unknown. Electrophysiological characterization of the active properties of these neurons throughout adulthood will help to address the biophysical and computational principles of the neuronal integration. Here we provide a database of whole-cell intracellular recordings from 315 neurons located in the supragranular layers (L2/3) of the primary somatosensory cortex in adult mice (9-45 weeks old) from both sexes (females, N=195; males, N=120). Data include 361 somatic current-clamp (CC) and 476 voltage-clamp (VC) experiments, recorded using a step-and-hold protocol (CC, N=257; VC, N=46), frozen noise injections (CC, N=104) and triangular voltage sweeps (VC, 10 (N=132), 50 (N=146) and 100 ms (N=152)), from regular spiking (N=169) and fast-spiking neurons (N=66). The data can be used to systematically study the properties of somatic integration, and the principles of action potential generation across sexes and across electrically characterized neuronal classes in adulthood (see the Chapter 3). Understanding the principles of the somatic transformation of postsynaptic potentials into action potentials will shed light onto the computational principles of intracellular information transfer in single neurons and information processing in neuronal networks, helping to recreate neuronal functions in artificial systems.

## Data description

The primary somatosensory cortex (S1) encodes time-varying but spatially well-defined haptic information<sup>1</sup> from the mechanoreceptors in the skin, thereby creating a topographical neuronal representation of the tactile world<sup>2,3</sup>. Rodents, for example, locate tactile targets in their immediate environment by integrating information across these (whisker) representations in the barrel cortex<sup>4</sup>, where neurons in each cortical column preferably respond to a single whisker on the contralateral snout<sup>5</sup>. The supragranular layers (cortical layers 2/3, L2/3) of the barrel cortex is the first cortical network that integrates the sensory information across neighboring cortical columns, whiskers and whisk cycles<sup>6–10</sup>. This representation of the whisker contacts undergoes experience-dependent changes<sup>11–14</sup> and is altered in animal models of neurodevelopmental disorders<sup>15–17</sup>. Adaptive changes in the synaptic and modulatory drive could powerfully regulate the transformation of postsynaptic responses into action potentials, ultimately controlling how sensory information is transferred between cortical columns and cortical regions<sup>18</sup>.

Understanding the principles of neuronal information transfer in the supragranular layers will require a systematic analysis of the integrative properties of these cortical neurons. Thus far, however, slice experiments primarily focused on juvenile animals as it is widely considered that the neurons mature anatomically and electrophysiologically by the fourth postnatal week<sup>16,19–23</sup>. Here we provide a database of 837 experiments collected from 315 adult supragranular neurons that will help to address the principles of information processing by cortical neurons throughout the adulthood of mice. The database consists of whole-cell intracellular recordings in voltage-clamp (VC) and current-clamp (CC) configurations: while current-clamp somatic measurements bring insight into the properties related to action potential initiation, timing, rate, and pattern, voltage-clamp recordings provide information on the voltage-gated ion-channel dynamics. The database is best utilized to address the principles of information transfer in individual neurons (see e.g.<sup>18,24</sup>) and for the electrical characterization of adult cortical sensory neurons. It will serve synaptic, systems, computational and theoretical neuroscientist in search of the principles of information processing, transfer, and recovery in neuronal networks. The database is expected to create synergy with 1) the recently completed transcriptome<sup>25,26</sup> and proteome<sup>27,28</sup> of the supragranular layers of the barrel cortex, 2) computational models of the molecular changes that contribute to the maturation of synaptic communication in the same cortical region (e.g.<sup>29</sup>), 3) computational models of synaptic integration and action potential generation in the supragranular layers of the barrel cortex<sup>18</sup>, and 4) the high-resolution mapping of sensory representations using intrinsic signals in single trial resolution (e.g.<sup>30</sup>) resulting in a multi-scale analysis of the cortical organization, from molecules of chemical communication to network representations.

## Methods

Experiments that involve animals were conducted in accordance with the European Directive 2010/63/EU, national regulations in the Netherlands, and international guidelines on animal care and use of animals. *Pvalbtm1(cre)Arbr* (RRID:MGI:5315557) or *Ssttm2.1(cre)Zjh/J* mice (RRID:IMSR\_JAX:013044) from either sex (N=75 females, N=45 males, aged 9-54 weeks) were used from the local breeding colonies.

The mice were anesthetized with Isoflurane (1.5 ml/mouse) before the tissue was extracted and coronal slices of the primary somatosensory cortex, barrel subfield region is prepared (Figure 1). The procedures were as described before<sup>11,12,14,16,31</sup> with the exception that animals were intracardially perfused with ice-cold dissection solution containing (in mM) 108 choline chloride, 3 KCl, 26 NaHCO<sub>3</sub>, 1.25 NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O, 25 Glucose·H<sub>2</sub>O, 1 CaCl<sub>2</sub>·2H<sub>2</sub>O, 6 MgSO<sub>4</sub>·7H<sub>2</sub>O, 3 sodium pyruvate, after animals were deeply anesthetized, as assessed by pinch withdrawal reflex, heart and breathing rate. The brain was removed after decapitation and sliced coronally (300 micrometers in thickness) in the same ice-cold perfusion medium. The slices were then transferred to a chamber containing aCSF (in mM): 120 NaCl, 3.5 KCl, 10 Glucose·H<sub>2</sub>O, 2.5 CaCl<sub>2</sub>·2H<sub>2</sub>O, 1.3 MgSO<sub>4</sub>·7H<sub>2</sub>O, 25 NaHCO<sub>3</sub>, 1.25 NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O, aerated with 95% O<sub>2</sub>/ 5% CO<sub>2</sub> at 37°C. After 30 minutes, the slices were transferred to room temperature before whole-cell electrophysiological recordings started.

### *Whole-cell recordings*

Slices were continuously oxygenated and perfused with aCSF during recordings. The barrel cortex was localized and cells of interest in the supragranular layers were patched under 40x magnification in room temperature using HEKA EPC 9 and EPC10 amplifiers in combination with the Patch Master v2x90.2 data acquisition software. Patch clamp electrodes were pulled from glass capillaries (1.00 mm (external diameter), 0.50 mm (internal diameter), 75 mm (length), GC100FS-7.5, Harvard Apparatus) with a P-2000 puller (Sutter Instrument, USA) and used if their initial resistance were between 5 and 10 MOhm. They were filled with intracellular solution containing (in mM) 130 K-Gluconate, 5 KCl, 1.5 MgCl<sub>2</sub>·6H<sub>2</sub>O, 0.4 Na3GTP, 4 Na2ATP, 10 HEPES, 10 Na-phosphocreatine, 0.6 EGTA, and the pH was set at 7.22 with KOH. Current-clamp and voltage-clamp recordings were performed as described before<sup>32, 33</sup> and included four stimulus protocols (Figure 2).

### Current-clamp protocol

After establishing the current-clamp configuration, the resting membrane potential was set to -70 mV by direct somatic current injections, as required. The step-and-hold stimulation protocol included 10 steps of 500 ms long depolarization pulses (step size: 5, 10, 20, 40 or 60 pA) with an inter-sweep-interval of 6.5 s. The stimulus train was repeated 1-3 times with a 20 s interval. The drift, if any, in resting membrane potential during the recording was not corrected for. However, any neuron whose resting membrane potential varied more than 7 mV was not included in the database. The frozen-noise (FN) stimulation protocol involved somatic injection of the current that is the output of an artificial neural network of 1000 neurons, each firing Poisson spike trains in response to a 'hidden state' (see <sup>34</sup> for details, and <sup>35</sup> on how to generate the frozen noise input and analyze the data).

### Voltage-clamp protocol

The voltage-clamp stimulation protocols included step-and-hold and sawtooth (triangular) pulse injections (Figure 2). In both protocols, the membrane potential was clamped at -70 mV prior to somatic depolarization. In the step-and-hold protocols, 14 incremental steps of depolarizing pulses (10 mV/each) were delivered for a period of 250 ms with an interval of 20 s. Sawtooth pulses (range: -70 to 70 mV) were delivered at three frequencies (5, 10, 50 Hz) and consisted of five triangular pulses with peak-to-peak (P2P) distances of 200, 100, 20 ms, respectively. Each trial was repeated twice with 20 s interval.

**Figure 2. Experimental protocols and the hierarchical organization of the database.** The data is available online at <https://goo.gl/khkbB4> (DOI comes here). The database contains two subfolders, current-clamp and voltage-clamp, each of which has additional subfolders based on the stimulus protocols utilized in this study. Each dataset is provided in a .mat format and includes both voltage and current channels unless otherwise described. The stimulus delivered to the cells as well as the cell's response can be quantified from these variables.

### Data organization

Files in “.mat” (MATLAB) format containing the original traces from each experiment are organized in folders separated by the structure described in Figure 2. Metadata including the date and number of the experiments, the experimenter's initials, the animal's sex and age, the experimental protocol, the cell type, and the animal number are included in a tabulated format (.xlsx, Microsoft Excel; Supplemental Table 1). The experiments are named as the date\_prefix\_experiment number\_protocol number. All cells recorded from the same animal share the same experimental date.

The current clamp data (see “Current Clamp” folder) contains two subfolders, “Step Protocol” and “Frozen Noise”. Step Protocol data includes two channels (voltage and current), each of which includes two columns (timestamp and voltage/current values in volt and amp, respectively) for each repetition. Users can visualize both the current injected to clamp the soma and the observed voltage response. Data from each stimulus condition is saved under a separate variable which starts with “Trace\_a\_b\_c\_d” and includes information about a) the cell and experiment ID, b) the data type, c) the number of sweeps in each dataset, and d) the channels.

The “Frozen Noise” subfolder contains the voltage trace (i.e. neuronal response to the injected frozen noise), hidden state (activity in the modeled network responds to, see <sup>34</sup> for details) and the injected current trace. In addition, a MATLAB “struct” variable named “settings” is provided. Settings provide metadata under following “fields”: condition, experimenter, baseline (membrane potential value (in mV) at which the cell is kept with the baseline current injection), amplitude\_scalind (the scaling factor used to translate the output of the neural network, in pA value), tau (the time constant that defines the average switching speed of the hidden state), mean\_firing\_rate (of the artificial neurons), sampling\_rate (the acquisition rate (in kHz)), duration (in ms), FLAG\_convert\_to\_ampere (a binary value that is 1 if the output was converted into Ampere), and cell\_type (regular spiking vs fast spiking).

The voltage clamp folder includes two subfolders: VC Step (voltage step-and-hold) and VC Sawtooth, the latter containing 3 subfolders with recordings from experiments with triangular sweeps at 3 frequencies (5, 10 or 50 Hz). Data in the Voltage Clamp folder is organized similarly to data in the Current Clamp folder, and variable naming follows the formatting rules described above.

### Cell type classification

K-means clustering (cluster count=2; the number of repetitions=10) was performed to classify neurons into fast-spiking and regular spiking neurons, using current clamp step-and-hold recordings. The clustering was based on the maximum firing rate reached during the current step injections and on the mean spike half-width across all stimulus steps during the current-clamp, step-and-hold protocol. Please note that the cell classification is solely provided to help the user to navigate the data. We do not claim that neurons can be necessarily electrically classified in a binary fashion, nor do we claim that commonly utilized clustering approaches are optimal for accurate (albeit broad) classification of excitatory (mostly regular spiking) and inhibitory (predominantly fast-spiking) neurons.

**Re-use potential**

The dataset is rich in information regarding current versus voltage dynamics in adult cortical neurons. The independent variables in the database are the sex and age of the animal. While current-clamp experiments provide information about sub- and suprathreshold voltage dynamics, the voltage-clamp experiments are informative about the ionic conductances that lead to activation or inactivation of neurons.

In the step-and-hold current-clamp experiments, the voltage responses can be quantified using subthreshold (e.g. amplitude, latency, duration of the postsynaptic potential) and suprathreshold (e.g. interspike interval adaptation, spike count, spike half-width) responses to somatic current injection (Figure 3). Because multiple stimuli with incrementally increasing current intensities are delivered, cellular responses can be mapped onto stimulation intensities, allowing users to study input/output curves for the parameters of interest.

Action potentials can be studied both in terms of their shape (e.g. waveform, rise and decay slope, amplitude of the positive and negative peaks, the half-width of spike) and temporal response properties (that allow quantification of the rate and timing of action potentials during synaptic activation). Since adaptation to a sustained current injection is commonly used as a criterion to classify neurons, the data provides an inclusive database for the electrical classification of adult neurons, creating synergy with other publicly available databases, e.g. Neurodata Without Borders <sup>36</sup> and the Allen Institute Cell Type database <sup>37</sup>. The data can be used independently or in the context of computational models of neural networks, a broad selection of which can be found in the ModelDB database <sup>38</sup>. In addition to sustained somatic depolarization, the current-clamp database also includes “frozen noise” injections, during which a time-varying current was injected into the recorded neuron (Figure 4). The injected current was generated using an artificial neural network (see <sup>34</sup> for details) of 1000 neurons, each one firing spike trains from an inhomogeneous Poisson process, responding to a binary hidden state which represents the presence or absence of an external stimulus. The activity of all the neurons in the artificial network is integrated and the resulting current is corrected for the baseline current required to keep the patched neuron at -70mV. This summed current is injected to the patched soma. A major utility of the frozen noise protocol is that it allows direct quantification of neuronal information transfer <sup>10,34</sup>. Compared to other metrics of neuronal information transfer <sup>18,39,40</sup>, this approach enables bias-free quantification of information with a short (3 or 6 min) stimulation protocol <sup>34</sup>.

**Figure 3. Electrical characterization of the spiking response in current-clamp experiments.** The parameter space is shown as a hierarchical tree. Variables shown in blue are used for the data displays. AHP = afterhyperpolarization. “Compression” is a normalized metric that can be calculated as the difference between observations (e.g. spike timing) over the duration of stimulus. In the case of “latency compression” it is calculated as the temporal difference

between the first and last action potential divided by the stimulus duration. “Adaptation” is the relative change in the observed variable, normalized to the first event. For example, in the case of spike amplitude adaptation, it is calculated as  $(AP_{amp\_first} - AP_{amp\_last}) / AP_{amp\_first}$ . All characteristics are measured relative to the stimulus amplitude (the current injected, in pA). Membrane potential traces on the top-right are the responses to incremental current injections, superimposed on top of each other. The data below the raw traces represents the number of action potentials and the amplitude of the injected current across the 10 step-and-hold stimuli in this experiment (Filename: 170130\_AL\_133).

In the database, experimental data recorded from our frozen noise protocol include the recorded membrane potential voltage, the hidden state and the current injected into the neurons (Figure 4). Thus, the user can perform forward and reverse modeling to predict the neuronal response and to study neuronal dynamics in the adult neocortex.

**Figure 4. Frozen noise injection in current-clamp configuration.** Representative recording from a single neuron (experiment 171207\_NC\_146). Top row: Binary representation of the hidden state that forms the input to an artificial neural network with 1000 point neurons, firing action potentials following an inhomogeneous Poisson process (see <sup>34</sup> for details). Middle row: the synaptic current generated by the artificial network that was injected into the recorded neuron. Bottom row: the membrane potential response of the recorded neuron.

Going beyond the voltage dynamics in the adult neurons, the database also provides insight into the ionic currents that flow through the membrane. With the triangle shaped VC-Saw protocol (Figure 5), it is possible to measure the activation threshold of the currents flowing through the membrane, by assessing when deviations from the expected sawtooth shape occur. Additionally, it is possible to compute: amplitudes and latencies of the events,

peaks half-widths, the percentage difference between consecutive events and the total number of events in each sweep. Other features could also be extracted from the dataset depending on the researchers' interests.

**Figure 5. Voltage-clamp sawtooth protocol.** Top row: Current trace from a representative experiment (180412\_AB\_53\_ST). Figurines, left to right, are measurements of the first peak amplitude, first peak latency, the half width of the first inward current, membrane potential at which the inward current is initiated, and the adaptation of the first event amplitude across the 5 (triangle) cycles. Data in the bottom three rows are from three different sawtooth speeds (10/50/100 ms, corresponding to 100/20/10 Hz stimulation). The five points in each figurine are calculated from the first inward current in each (triangle) cycle.

The current-voltage relationship was measured with voltage-clamp steps (Figure 6), which could be used to produce an I/V curve. The peak amplitude, latency, and peak half width can be extracted for the inward currents observed during the sustained depolarization of the soma.

**Figure 6. Step-and-hold protocol in voltage-clamp preparation.** Top panel shows data from a representative experiment (170915\_AB\_5\_VC). Every other figurine shows one of the analyzed features, including the amplitude of the peak, temporal delay between the stimulus onset and the peak amplitude (i.e. latency), width of the evoked transient measured at half maximum as well as the current at every holding potential (I/V curve).

#### *Availability of Source Code and Requirements*

Project name: Rapid mutual information calculation using frozen noise injection

Project home page: <sup>35</sup>

Operating system: Platform independent

Programming language: MATLAB

Other requirements: MATLAB version 2017a or higher.

License: GNU GPL

RRID: SCR\_016558

#### *Availability of supporting data*

Snapshots of the database and code, including further supporting data is available in the GigaScience repository.

### Application scenarios

From the recordings available in this database, it is possible to quantify active the membrane properties of supragranular layer neurons to infer current and voltage dynamics during somatic depolarization.

Network development is based on processes of self-organization that are highly dependent on sensory stimuli and experience <sup>2</sup>. Such plasticity is not limited to early life development. From the voltage-clamp and current-clamp experiments, it is possible to infer the biophysical properties of layer 2/3 pyramidal neurons of the adult somatosensory cortex under baseline conditions, in the absence of altered sensory experience.

The focus on adult neurons brings a new perspective to the study of membrane properties, as data from these mature ages are still scarce. The dynamics of the active electrical properties of the membrane can be accessed as a function of different developmental time points and/or sex, and the recorded data can be used as virtual neurons in dynamic-clamp experiments.

In a computational approach, spiking properties described herein could be used for biomimetic modeling of diverse networks, facilitating the study of computational roles of circuit motives. Moreover, applying the principles of information transfer and recovery to the data might help recreate neuronal functions in artificial systems.

### Limitations

Neurons in this dataset originate from regular spiking and fast spiking neurons, however, there is no anatomical characterization of the neuron type studied. The database is focused on Layer 2/3 of the somatosensory cortex as a model region and does not allow the study of neuronal information processing across different cortical regions in isolation. However, the user might consider comparing data across different regions and species by utilizing the other publicly available databases, e.g. Neurodata Without Borders <sup>36</sup>, the Cell Type database <sup>37</sup> of the Allen Institute and the Collaborative Research in Computational Neuroscience data sharing initiative <sup>41</sup>.

# Chapter 3

**Electrical characterization of the  
supragranular layer neurons in the adult  
mouse barrel cortex**

Neurons have diverse molecular, anatomical and electrical characteristics throughout the brain. Functional classification of neurons will help to determine the building blocks of neuronal circuits, in particular in heterogenous circuits like the sensory cortices in the neocortex. Here, taking advantage of a recently introduced intracellular recording database (see Chapter 2), we perform a systematic classification of the cell-types in the supragranular layers of the barrel cortex. Unlike the prior efforts for electrical classification of the neuronal cell-types, we define the neuronal sub- and suprathreshold responses to varying, but bandwidth limited, somatic depolarization in a high dimensional space ( $N=139$ ). We determine the minimum number of dimensions that are required to represent the data ( $N=15$ ), reduce the dimensionality while maintaining cluster separation and finally electrically compare the cell-classes. The results show that the best predictor for cell classification is the adaptive change observed in the membrane potential during varying somatic depolarization. The neurons can be classified into 10 cell-classes using 5 dimensions. These results argue that systematic variations in neural responses upon varying somatic depolarization states is an understudied but an important dimension in cellular classification.

The neurons in layer 2/3 the barrel cortex of rodents are involved in integrating information that originates from the sensory periphery with the information generated elsewhere in the brain <sup>1-4</sup>. They carry spatial and temporal information about contacts with an object, tactile features of the object and the whisker position in parallel <sup>5</sup>. Given their importance for the neural processing of sensory information, one of the major goals of systems neuroscience is to identify the building blocks of the somatosensory circuits.

Neurons are commonly classified according to their anatomical features, molecular fingerprints, as well as passive and active electrical properties <sup>6-11</sup>. For example, inhibitory neurons in the supragranular (L2/3) of the juvenile primary somatosensory cortex can be anatomically divided into 8 distinct classes based on their shape, organization, and localization of the projections, while 5 sub-classes can be distinguished among the pyramidal neurons <sup>6,12,13</sup>. Given the considerable molecular and biochemical diversity of neurons <sup>6,9,10,14,15</sup>, the combinatorial classification of neurons based on molecular fingerprints and anatomical features arguably results in the overestimation of the functional subclasses in the network. For example, neurogliaform neurons can be classified as a single subpopulation of inhibitory neurons when both their anatomical features and the expression of the 5-Hydroxytryptamine Receptor 3A receptors are considered. However, because these neurons also express Glutamate Decarboxylase 1 and Vasoactive Intestinal Peptide at varying rates, the neurogliaform neurons can be further sub-classified <sup>10</sup>. The expression of the molecular markers is often subject to experience-dependent plasticity <sup>1</sup>, therefore, cellular classification based solely on molecular markers might confound the clustering efforts. Considering that action potential rate and timing are the means of neuronal communication in synaptically coupled networks, active electrical properties of neurons could instead be used to determine the functional subclasses of neurons.

Cellular classification based on active electrical properties of neurons necessarily requires redefining continuous voltage (or current) time-series into variables (also known as descriptors, features, dimensions), e.g. action potential threshold, amplitude, spike half-width. Although the selection of features is arbitrary, this approach, combined with various clustering methods, has been successfully used to electrically classify neurons before <sup>14,16-21</sup>.

In previous studies, the neural responses to sustained somatic activation (or inactivation) have been studied upon depolarization (or hyperpolarization) at a constant single stimulus intensity. However, given the prominent voltage-gated conductances the integrative properties of neurons are likely to vary depending on the amplitude of the sustained depolarization.

<sup>1</sup> The transcriptome and the proteome of the supragranular and granular layers of the barrel cortex in control conditions and after sensory deprivation are freely available at [barreломics.science.ru.nl](http://barreломics.science.ru.nl)

Therefore, in this study, we electrically characterized the supragranular neurons in the primary somatosensory cortex using the database of 213 neurons described in Chapter 2. Current-clamp recordings across discrete steps of somatic depolarizations resulted in a varying number, rate, and pattern of action potentials in single neurons. Clustering performed after the identification of the features that describe supra- and subthreshold voltage dynamics within and across depolarization steps showed that adaptive changes in voltage dynamics are a powerful predictor of cell classes in the somatosensory cortex. Based on the classification performed in this dataset, we argue that the supragranular layers of the barrel cortex consist of 10 electrically distinguishable cell types.

### **Materials and methods**

Animal experiments were realized as approved by the European Directive 2010/63/EU, national regulations in the Netherlands, and international guidelines on animal care and use of animals.

The electrophysiological methods are described in detail in Chapter 2. In short, Pval-cre and SSt-cre mice ( $n = 120$ ) between 9 and 54 weeks, 37.5% male were anesthetized with Isoflurane (10 ml/mouse) and the depth of the anesthesia was assessed by pinch withdrawal before perfusion in cooled solution containing (in mM): 10.8 choline chloride, 0.3 KCl, 2.6  $\text{NaHCO}_3$ , 0.125  $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ , 2.5 Glucose. $\text{H}_2\text{O}$ , 0.1  $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ , 0.6  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , 0.3 Na.pyruvate. After extraction, the barrel cortex was sectioned coronally (thickness: 400  $\mu\text{m}$ ) and slices were transferred to a chamber containing ACSF (in mM): 120 NaCl, 3.5 KCl, 10 Glucose. $\text{H}_2\text{O}$ , 2.5  $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ , 1.3  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , 25  $\text{NaHCO}_3$ , 1.25  $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ , aerated with 95%  $\text{O}_2$ / 5%  $\text{CO}_2$  as described before<sup>22,23</sup>. The slices were then kept in 37°C for 30 minutes and subsequently another 30 minutes (minimum) in room temperature before the whole-cell recordings. During incubation and electrical recordings, the slices were continuously oxygenated and perfused with ACSF. The barrel cortex was located using the 20x lens and the pyramidal cells were patched with a 40x lens.

For the electrophysiological recordings, pipettes were pulled from borosilicate glass tubing with a P-2000 puller (Sutter Instrument, USA) and used if their initial resistance were between 5-9 MOhm. They were filled with (mM): 130 K-Gluconate, 5 KCl, 1.5  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ , 0.4 Na3GTP, 4 Na2ATP, 10 HEPES, 10 Na-phosphocreatine, 0.6 EGTA, and the pH was set at 7.22 with KOH. We used conventional current and voltage clamp<sup>24,25</sup> configurations. Series resistances were between 10-75 MOhm and bridge balance was not compensated. After establishing the current-clamp configuration, the current was kept constant to keep the membrane potential at -70 mV and 10 steps of 20-40 pA current injections were somatically delivered for a duration of 500 ms. Each stimulus intensity was repeated 1-3 times with a 20 s

interval. If the membrane potential varied more than 7 mV during the course of the recording the cell was excluded from the database.

### *Description of the feature space*

All data analysis was performed off-line using custom-written routines in MATLAB. Voltage traces corresponding to somatic current injection epochs (500 ms/sweep) were used for the quantification of the active electrophysiological properties of neurons (Figure 1). A total of 139 features were extracted from each neuron (see Supplemental Table 1). Seventy of these features were descriptors of the sub- and suprathreshold responses in single depolarization sweeps. The remaining 69 captured the dynamical nature of the change in somatic voltage dynamics across depolarization states.

**Figure 1. Primary features of somatically evoked action potentials.** An example voltage trace and the description of primary features. See Supplemental Table 1 for a complete description. AP = action potential, ISI = interspike interval; AHP = afterhyperpolarization peak.

To estimate the adaptive changes in membrane potential across the 10 somatic depolarization states, we performed a “best fit” analysis. The results showed that the overwhelming majority (i.e. 67/70) of the dynamics can be best approximated by a linear fit, although the slope across the feature space varied. Those features that are best estimated with a logistic or exponential function, can also be approximated with a linear fit albeit at a cost of increased residuals. To ensure a uniform comparison across the feature space, we fitted all dynamical parameters (i.e. varying with stimulus amplitude) with linear kernel, and used the slope and onset value of each fit as descriptors, obtaining a total of 139 parameters (the parameter representing the “lowest current step at which the cell fired an AP” does not have a fit value).

### *Dimensionality reduction*

Dimensionality reduction prior to clustering allows maximum occupancy of each cluster and smaller cluster boundaries, given that those clusters that are weakly connected are unlikely

to converge if clusters are undersampled. Therefore, to estimate the minimum number of dimensions required to describe the data, we performed a Principal Component Analysis (PCA). We computed the eigenvalues of the whitened PCA covariance matrix, obtaining the lower boundary estimation, i.e. 15, as described before <sup>26</sup>:  $\text{Dim} = (\sum_i \lambda_i)^2 / (\sum_i \lambda_i^2)$ .

To reduce the dimensionality in the feature space, we applied an empirically defined threshold of 0.6 on the Pearson correlation coefficients, computed pairwise across all parameters. The remaining 35 parameters are listed in Supplemental Table 1. Given the lower limit estimate of 15 and the higher limit of 139, and a dataset of 213 neurons, this feature space represents a sufficiently small dimensionality to perform the initial clustering.

### *Clustering*

To sort neurons into cell-classes, we used a hierarchical clustering approach where neurons were first sorted into 50 classes using k-means clustering <sup>27</sup>, which were subsequently merged iteratively using maximum likelihood estimations as described below and before <sup>28</sup>. This approach ensured that the similarity within cell-clusters and dissimilarity between clusters were maximized.

K-means clustering was performed after standardizing the data so that each feature had a mean of zero and a standard deviation of one. After clustering, those cell-clusters that had less than 10 cells were removed and its members were reassigned to the closest cluster based on Z-distance minimization <sup>26</sup>. This entire process was repeated 10000 times to calculate the variance in cluster assignments, which was subsequently used to determine the final cell-clusters based on maximum likelihood (ML) estimations, assigning each cell to the cluster with the highest probability of containing it. If, after the ML assignment, there were any clusters with less than 10 cells, the entire procedure was repeated again but this time ML clusters were used as the starting clusters.

### *Feature ranking*

To systematically evaluate what features are most informative for the classification of neurons, and provide a simplified set of criteria for post-hoc replicability across different datasets, we searched for the most informative features. To do so we computed the mean Z-distance between any given clusters for any combination of 5 features that survived that dimensionality reduction (from 139 to 35). As the final step, we ran the standard k-means algorithm, with the number of clusters estimated with the maximum likelihood agglomerative clustering, for all feature sets ( $N_s = [139 \ 35 \ 5]$ ) and compared them by computing the Z-distance between them.

## Results

To approximate the number of cell classes in the supragranular layers of the adult barrel cortex, we employed a hierarchical clustering approach on voltage traces recorded intracellularly in acute cortical slices.

### *Dimensionality reduction for neuronal classification*

The neuronal response to somatic current injections was approximated by 139 dimensions that represent the response dynamics within and across stimulus intensities (i.e. the amplitude of the current injection, see Supplemental Table 1). To determine whether neurons can be clustered with high confidence in this high-dimensional feature space, we performed the k-means clustering and a single iteration of ML-based cluster merging (see Materials and Methods for details). The quantification of the occupancy for each cluster (Figure 1A) showed a heteroscedastic distribution. The probability of a given neuron to be assigned to any given cluster (Figure 1B) did not follow a uniform distribution, and only a subset of neurons was clustered with high confidence (Figure 1C). These observations support the notion that clustering in a high-dimensional space results in clusters with a small (minimal) inter-cluster distance. Accordingly, under these constraints, cluster identification is a probabilistic inference where each neuron has a particular probability distribution to be associated with a finite number of clusters (Figure 1C).

**Figure 2. Clustering in high-dimensional feature space is a probabilistic approach to cell-type identification.** (A) Sum of the probabilities of all the neurons to belong to a specific cluster. (B) The maximum probability for each neuron to belong to any cluster (indicative of certainty of cluster assignment). (C) The probability of each cell to be assigned to a specific cluster after the merging procedure, counted after 20000 mergings iterations.

Clustering performance can be improved by either reducing the dimensionality of the feature space or by increasing the sampling size (i.e. number of neurons) to minimize the distance between the members of a given cluster while increasing the inter-cluster distance. Given the 213 neurons available in this dataset, we opted to reduce the dimensionality of the feature space.

To estimate the minimum number of features required to describe the data, we computed the dimensionality of the dataset based on the eigenvalues of the covariance matrix (see Materials and Methods for details), which showed that a minimum of 15 features is required to maximally reconstruct the data defined in 139 dimensions. To identify these features

we computed the pairwise Pearson correlation across all variables. The correlation matrix (Figure 3A) showed that 12 subsets of features are highly correlated. Using an empirically determined threshold of 0.6, we identified “weakly” correlated parameters ( $N=35$ ; see Supplemental Table 1) and repeated the neuronal clustering in this lower-dimensional feature space. The 213 neurons were grouped into 10 clusters (Figure 3B) that are well separated from one another (Figure 3C).

**Figure 3. Dimensionality reduction in the feature space and neuronal clustering in a lower dimension.** (A) The pairwise correlation coefficient between all 139 variables represented as a matrix. Left: Bidirectional correlation coefficient. Right: The correlation matrix on an absolute scale. (B) The distribution of the neurons across 10 clusters identified after clustering using 35 spike features. (C) The pairwise Euclidean distance between the cluster centroids after standardization.

The 35 features used for clustering is still significantly larger than the theoretical minimum number of features (i.e. 15) required to describe this dataset. To rank the relevant contribution of each feature to the clustering performance we have repeated clustering using only 5

features at a time in a combinatorial space. Across the 324632 combinations, all informative features are the variables which approximate the cell behavior across current injection steps (Figure 4A).

**Figure 4. Ranking features for their contribution to cluster separation and clustering with 5 most informative features.** We considered every possible combination of 5 parameters, in the 35 remaining after the correlation analysis. We computed new cluster assignments, using the method described before, but in the 35-parameter space, next we computed the Z-distance between the clusters in the space that is given by the projection on each of these 5-parameter subspaces. The combination of 5 parameters that results in the highest average Z-distance between clusters is considered to be the most informative. **(A)** Ranked order of features, computed by counting the appearance of each one, in the 5 parameters combinations, ordered by their averaged Z-distance. **(B)** Neurons were

sorted into 13 clusters. (C) The pairwise Euclidean distance between the cluster centroids.

To quantify the clustering performance with a subset of features, we repeated the clustering one final time but with five features (i.e. slope of the linear fit of the Absolute Firing Rate and Maximum AHP Peak Amplitude, the onset values of AP Latency Window, AP HalfWidth Mean and AHP Peak Latency Mean). The results showed that except for one neuron (appears in blue in Figure 4B), all neurons had a unique cluster identity, suggesting that in the 5 dimensional space neurons can still be grouped with high-confidence into well-separated clusters (Figure 4C).

#### *Neuronal electrical identity depends on the somatic depolarization amplitude*

The feature space that best predicts the clustering performance, i.e. most informative feature combination, exclusively includes variables that are analytical descriptions of the adaptive changes observed in spiking across somatic (membrane) depolarization states (Figure 4A). This observation suggests that the separation between clusters might depend on stimulus amplitude. Because voltage-gated conductances help maintain membrane depolarization, ensure repolarization and contribute to the action potential generation, a sustained depolarization of the membrane potential might change the electrical signature of the neuron<sup>29-31</sup>. Therefore, to quantify the discriminability of the clusters across the discrete somatic depolarization states, we calculated the average pairwise Z-distance between clusters (Figure 5).

**Figure 5. Cluster separation varies with membrane polarization state.** The Z-distance between clusters were calculated across all clusters and across stimulus amplitude. Nine representative features and the degree of separation between clusters are shown.

The results show that the cluster separation varies with the membrane potential such that in those feature spaces based on spike timing and its derivatives, the cluster separation

gradually improves as the amplitude of somatic current injection is increased. Spike threshold and firing rate across somatic depolarization states distinguish a non-overlapping subset of clusters which differentially adapt to the changes in the membrane states. The duration, amplitude, and latency of the after-spike hyperpolarization (AHP) are all regulated, expectedly, across the different membrane potentials; while the suppression of the AHP peak amplitude in more depolarized membrane states results in better discriminability of the clusters during weak somatic depolarization; both the peak latency and the duration of the AHP contribute to better cluster separation in more depolarized membrane states. These results argue that the electrical signature of neurons, hence the performance of clustering based on the spiking dynamics of neurons, varies across the membrane states.

### *Neuronal classes in the adult primary somatosensory cortex in layers 2/3*

To identify the functional classes of adult cortical neurons in the supragranular layers of the primary somatosensory cortex, we have deployed the hierarchical clustering described above and assigned each neuron to a cluster. Ten clusters contained 10 or more units. To systematically compare the changes in the spiking responses across the membrane states, we described the electrical responses to somatic current injections using features that are among the most informative dimensions for clustering.

As previously shown<sup>14,19,20,32</sup>, binary classification of putative excitatory (regularly spiking) and putative inhibitory (fast-spiking) neurons can be achieved using firing rate/inter-spike interval, action potential half-width, or any combination thereof (Figure 6). The amplitude of the afterhyperpolarization (AHP) peak allows further classification of the putative inhibitory neurons into three sub-classes based on the rate adaptation upon somatic depolarization (Figure 6). Although all three sub-classes have a comparable AHP duration, which is shorter than that of all putative excitatory neurons, and quickly reach the peak latency during membrane repolarization, their AHP amplitude follows a gradient and is not suppressed considerably with the increased depolarization of the membrane (Figure 6).

In terms of the molecular and biochemical complexity, inhibitory neurons are significantly more diverse than their excitatory counterparts<sup>6,9,10,14,15</sup>. Electrophysiologically, however, our findings now indicate that excitatory neurons are more diverse. Seven of the ten clusters generate action potentials at lower rates than putative inhibitory neurons, and the AP width is at least twice as large as that of inhibitory neurons. The significant variability among excitatory neurons' spiking patterns (Figure 6) might be attributed to the properties (i.e. subchannel composition), density and distribution of voltage-gated sodium and potassium channels (e.g. in the case of action potential half-width, action potential latency, action potential threshold), the adaptive changes in voltage-gated conductances across depolarization states (resulting in

action potential threshold variation) or differences in the membrane integration time constant (e.g. interspike interval). This variability between the putative excitatory neurons might also be due to anatomical or experience-dependent changes across cortical neurons. Independent from the underlying cause, these results argue that adult excitatory neurons are more diverse than the inhibitory neurons in the primary somatosensory cortex.

**Figure 6. Spiking characteristics of identified clusters in the primary somatosensory cortex of the adult mouse.** All data is from the cortical layers 2/3 of the barrel cortex. Clusters 3,6,8 are putatively inhibitory.

## Discussion

The responses of (cortical) neurons are shaped by both their intrinsic biophysical properties and their position and connectivity in the network<sup>33–35</sup>. During development, but also throughout the adult life of an animal, several mechanisms including homeostatic and neural plasticity mechanisms constantly update the neuron's properties in order for the neuron to be able to function properly. These changing properties include its biophysical properties (i.e. what ion channels and receptors are expressed in the membrane and in what quantities, see for instance<sup>36</sup>), its connectivity (i.e. to what neurons it is connected and how strongly) as well as its morphology. Therefore, we expect that structural and functional correlations between neurons<sup>18,37,38</sup> results in neural properties that group together so that the cell can perform its functions, corresponding to 'neural cell classes'. Here we described such a grouping of neurons, as we identify three putative inhibitory and seven putative excitatory cell classes in the cortical layers 2/3 of the adult primary somatosensory cortex.

Neurons in a cluster can plausibly adopt different strategies in order to perform certain functions<sup>39,40</sup>, resulting in gradual differences between neurons rather than well-separated 'clusters' of properties as we observed among the excitatory neurons (also see<sup>41</sup>). Finding the neural properties that group together, i.e. 'clustering' our high-dimensional dataset, is a non-trivial task, where the experimenter necessarily has to make non-obvious choices about which clustering method to use and how to set the meta-parameters of the clustering algorithm. Often, the 'ground-truth' is not known, so it is difficult to assess the quality of the chosen method. Therefore, it is important to choose the method with some knowledge of the dataset<sup>42</sup>. For instance, because of the continuous nature of our data, clustering methods purely based on distance, such as tSNE<sup>43</sup>, do not perform well. An extra difficulty in our dataset is that it is large for an in vitro dataset, but relatively small in relation to the number of dimensions. Therefore, we chose a combination of a simple but well understood and easy to interpret automatic method (k-means clustering) together with a method that was specific for this dataset (merging small clusters until each cluster had at least 10). This approach allowed us to perform clustering in a lower dimensional space, i.e. by considering less number of features. Repeating the clustering in a larger dataset, when it becomes available, will help to identify those neuronal clusters that are sparsely populated in our iteration of the clustering.

Even though the high-dimensional clustering of cell properties gives many insights on its own, it is not always feasible in an experimental setup to measure so many cellular properties. Therefore, we asked: 'How can we minimize the number of measured cell properties, and still perform a cluster analysis with the same results as the high-dimensional clustering?'. For this, we had to perform dimensionality reduction. With the recent improvement of high-dimensional recording techniques, dimensionality reduction methods

beyond ‘simple’ principal component analysis have moved into the spotlight. Even though these types of analysis are mostly used for population recordings<sup>44,45</sup>, the same steps apply for high-dimensional in vitro single-cell data. The first step is looking into the ‘underlying’ dimensionality of the dataset: one should check that even though a (typically large) dataset is high-dimensional, the underlying principles are probably low-dimensional, allowing for a low-dimensional description. We showed here through the dimensionality calculation (see Materials and Methods) and the correlations between the measured parameters in our dataset that a lower-dimensional representation should be possible (Figure 3). The second step is to identify informative and less informative dimensions (Figure 4). Finally, one should perform a check on the dimensionality reduction: does the representation in low-dimensional space yield the same properties as in the high-dimensional space? Here we performed our clustering analysis both on the high- and low-dimensional representations of our data, and showed that neurons are classified into well separated clusters before and after the dimensionality reduction (see Figure 3 vs 4). Thus, the clustering approach presented herein is unlikely to be biased by the sampling size or the number of features used for the classification. Future application of this clustering approach in neurons recorded across brain regions and developmental periods will help to address whether these cell classes are universal. Using these identified cell classes and their response properties in computational network models will help to develop more advanced, biologically realistic networks, starting with a model of the somatosensory cortex of the rodents.

## Supplementary materials

**Supplemental Table 1.** Principal features of action potentials. Each quantity is measured over increasing current injections step. For each quantity (with the exception of the 1st, which has only a single scalar value) both the starting value as well as the slope of the linear fit over the current injections are used as parameters (for a total of 139 parameters). AP = action potential; AHP = afterhyperpolarization current; ISI: interspike interval. The 35 parameters that were selected after the correlation analysis are in *italics*.

1	Current necessary for 1st AP [pA]	the lowest current step at which the cell fired an AP [pA]
2	AP count	the number of APs fired through the stimulation
3	<i>Absolute FR [Hz]</i>	the number of APs divided by the stimulus duration
4	Instantaneous FR [Hz]	the instantaneous firing rate over the stimulation
5	AP Latency of 1st spike [ms]	the time interval between the start of the stimulation and the 1st AP generated.
6	AP Latency of last spike [ms]	the time interval between the start of the stimulation and the last AP generated.
7	<i>AP Latency of window [ms]</i>	the time interval between first and last AP generated
8	AP Latency compression	onset latency between the first and last spikes, divided by the stimulus length
9	ISI minimum [ms]	the minimum ISI between 2 consecutive APs over the stimulation
10	ISI maximum [ms]	the maximum ISI between 2 consecutive APs over the stimulation
11	<i>ISI mean [ms]</i>	the mean ISI between 2 consecutive APs over the stimulation
12	ISI median [ms]	the median ISI between 2 consecutive APs over the stimulation
13	ISI adaptation rate [%]	(First ISI - Last ISI) / First ISI
14	AP Threshold of 1st spike [mV]	the threshold at which the 1st AP of the AP train is generated, computed as the peak of the 2nd derivative of the membrane potential.
15	AP Threshold of last spike [mV]	the threshold at which the last AP of the AP train is generated, computed as the peak of the 2nd derivative of the membrane potential.
16	AP Threshold minimum [mV]	the minimum threshold at which an AP is generated during the AP train, computed as the peak of the 2nd derivative of the membrane potential.
17	AP Threshold maximum [mV]	the maximum threshold at which an AP is generated during the AP train, computed as the peak of the 2nd derivative of the membrane potential.
18	<i>AP Threshold mean [mV]</i>	the mean threshold at which an AP is generated during the AP train, computed as the peak of the 2nd derivative of the membrane potential.

19	AP Threshold median [mV]	the median threshold at which an AP is generated during the AP train, computed as the peak of the 2nd derivative of the membrane potential.
20	AP Threshold adaptation rate [%]	(First AP Threshold - Last AP Threshold)/ First AP Threshold
21	AP Half-Width of 1st spike [ms]	the width of the 1st AP at half height
22	AP Half-Width of last spike [ms]	the width of the last AP at half height
23	AP Half-Width minimum [ms]	the minimum half-width of the whole AP train
24	AP Half-Width maximum [ms]	the maximum half-width of the whole AP train
25	<i>AP Half-Width mean</i> [ms]	the mean half-width of the whole AP train
26	AP Half-Width median [ms]	the median half-width of the whole AP train
27	AP Half-Width adaptation rate [%]	(First AP Half-Width- Last AP Half-Width)/ First AP Half-Width
28	AP Amplitude of 1st spike [mV]	the amplitude of the 1st AP of the AP train, computed as $ \max - \text{baseline} $
29	AP Amplitude of last spike [mV]	the amplitude of the last AP of the AP train, computed as $ \max - \text{baseline} $
30	AP Amplitude minimum [mV]	the minimum amplitude of the whole AP train, computed as $ \max - \text{baseline} $
31	AP Amplitude maximum [mV]	the maximum amplitude of the whole AP train, computed as $ \max - \text{baseline} $
32	<i>AP Amplitude mean</i> [mV]	the mean amplitude of the whole AP train, computed as $ \max - \text{baseline} $
33	AP Amplitude median [mV]	the median amplitude of the whole AP train, computed as $ \max - \text{baseline} $
34	AP Amplitude of adaptation rate [%]	(First AP Amplitude - Last AP Amplitude)/ First AP Amplitude
35	AHP Peak Latency of 1st spike [ms]	the time interval between the return to baseline of the voltage after the 1st AP of the APs train, and its corresponding AHP peak.
36	<i>AHP Peak Latency of last spike</i> [ms]	the time interval between the return to baseline of the voltage after the last AP of the APs train, and its corresponding AHP peak.
37	<i>AHP Peak Latency minimum</i> [ms]	the minimum time interval between the return to baseline of the voltage after the APs of the APs train, and its corresponding AHP peak.
38	AHP Peak Latency maximum [ms]	the maximum time interval between the return to baseline of the voltage after the APs of the APs train, and its corresponding AHP peak.
39	<i>AHP Peak Latency mean</i> [ms]	the maximum time interval between the return to baseline of the voltage after the APs of the APs train, and its corresponding AHP peak.
40	<i>AHP Peak Latency adaptation rate</i> [%]	(First AHP Peak Latency - Last AHP Peak Latency)/ First AHP Peak Latency

41	AHP Peak Amplitude of 1st spike [mV]	the difference between the peak of the AHP corresponding to the 1st AP of the APs train, and the baseline membrane potential.
42	AHP Peak Amplitude of last spike [mV]	the difference between the peak of the AHP corresponding to the last AP of the APs train, and the baseline membrane potential.
43	AHP Peak Amplitude minimum [mV]	the minimum difference between the peak of the AHP corresponding to the APs of the APs train, and the baseline membrane potential.
44	<i>AHP Peak Amplitude maximum</i> [mV]	the maximum difference between the peak of the AHP corresponding to the APs of the APs train, and the baseline membrane potential.
45	<i>AHP Peak Amplitude mean</i> [mV]	the mean difference between the peak of the AHP corresponding to the APs of the APs train, and the baseline membrane potential.
46	AHP Peak Amplitude adaptation rate [%]	(First AHP Amplitude - Last AHP Amplitude)/ First AHP Amplitude
47	AHP Duration of 1st spike [ms]	the time interval between the point where the membrane potential reaches baseline value, after an AP, and when it reaches baseline value, after the corresponding AHP, measured for the 1st AP of the APs train.
48	AHP Duration of last spike [ms]	the time interval between the point where the membrane potential reaches baseline value, after an AP, and when it reaches baseline value, after the corresponding AHP, measured for the last AP of the APs train.
49	<i>AHP Duration minimum</i> [ms]	the minimal time interval between the point where the membrane potential reaches baseline value, after an AP, and when it reaches baseline value, after the corresponding AHP, for the whole APs train.
50	AHP Duration maximum [ms]	the maximum time interval between the point where the membrane potential reaches baseline value, after an AP, and when it reaches baseline value, after the corresponding AHP, for the whole APs train.
51	<i>AHP Duration mean</i> [ms]	the mean time interval between the point where the membrane potential reaches baseline value, after an AP, and when it reaches baseline value, after the corresponding AHP, for the whole APs train.
52	<i>AHP Duration adaptation rate</i> [%]	(First AHP Duration - Last AHP Duration)/ First AHP Duration
53	AHP Integral of 1st spike [ms*mV]	the integral of the AHP of the 1st AP in the APs train.
54	AHP Integral of last spike [ms*mV]	the integral of the AHP of the last AP in the APs train.
55	AHP Integral minimum [ms*mV]	the minimum integral of the AHP of the APs train.
56	AHP Integral maximum [ms*mV]	the maximum integral of the AHP of the APs train.
57	AHP Integral mean [ms*mV]	the mean integral of the AHP of the APs train.

58	AHP Integral adaptation rate [%]	(First AHP Integral - Last AHP Integral)/ First AHP Integral
59	<i>AHP Fall Slope of 1st spike</i> [mV/ms]	the slope of the decay phase of the AHP of the 1st AP in the APs train.
60	AHP Fall Slope of last spike [mV/ms]	the slope of the decay phase of the AHP of the last AP in the APs train.
61	<i>AHP Fall Slope minimum</i> [mV/ms]	the minimum slope of the decay phase of the AHP of the APs train.
62	<i>AHP Fall Slope maximum</i> [mV/ms]	the maximum slope of the decay phase of the AHP of the APs train.
63	<i>AHP Fall Slope mean</i> [mV/ms]	the mean slope of the decay phase of the AHP of the APs train.
64	<i>AHP Fall Slope adaptation rate</i> [%]	(First AHP Fall Slope - Last AHP Fall Slope)/ First AHP Fall Slope
65	AHP Rise Slope of 1st spike [mV/ms]	the slope of the rising phase of the AHP of the 1st AP in the APs train.
66	AHP Rise Slope of last spike [mV/ms]	the slope of the rising phase of the AHP of the last AP in the APs train.
67	AHP Rise Slope minimum [mV/ms]	the minimum slope of the rising phase of the AHP of the APs train.
68	AHP Rise Slope maximum [mV/ms]	the maximum slope of the rising phase of the AHP of the APs train.
69	AHP Rise Slope mean [mV/ms]	the mean slope of the rising phase of the AHP of the APs train.
70	AHP Rise Slope adaptation rate [%]	(First AHP Rise Slope - Last AHP Rise Slope)/ First AHP Rise Slope

# Chapter 4

**Activity dependent transcriptional  
regulation of the dopaminergic signaling in  
the somatosensory cortex**

Dopamine is a principal neuromodulator that contributes to various brain functions ranging from motor planning, coordination and execution to processing of reward and sensory stimulus. Whether dopaminergic signaling in sensory cortices is regulated by sensory experience is unknown. Here we addressed this question in the adult mouse primary somatosensory cortex by performing RNA sequencing in cortical columnar and laminae resolution after animals' sensory experience was controlled with bilateral single row whisker deprivation. The results showed that gene transcription in the dopaminergic signaling pathway (DSP) undergoes experience-dependent plasticity both in granular and supragranular layers. Sensory experience and sensory deprivation compete for the regulation of DSP transcription across the neighboring cortical columns, and that sensory deprivation induced changes in DSP signaling are topographically constrained. These results argue that dopaminergic drive originating from the midbrain dopaminergic neurons, targeting the sensory cortex, is subject to experience-dependent regulation and might contribute to the sensory deficits observed after dopaminergic cell loss in Parkinson patients.

Dopamine is a monoaminergic neurotransmitter that contributes to processing of sensory, motor, emotional states and higher cognitive functions 1–5. Dysfunctions of the dopaminergic synthesis and release are associated with various disorders that impair sensory processing, e.g. aggression and violence 6, Parkinson's Disease 7, addiction 8, attention deficit hyperactivity disorder 9,10.

Although how dopamine alters sensory processing is yet to be mechanistically understood, recent experiments 11 in the monkey prefrontal cortex showed that local application of dopamine regulates the integration of sensory information. Considering that sensory information (experience) powerfully modulates neuronal excitability in the primary somatosensory cortex 12–15 which projects to midbrain nuclei that release dopamine 16,17 if the dopaminergic signaling in the sensory cortices is modulated by experience, this would create a powerful close-loop between dopaminergic signaling and sensory processing. Such a regulatory close-loop might be the mechanism behind sensory integration loss upon dopaminergic depletion 18.

With its columnar organization and topographic representations, the whisker system of the rodents is a widely studied model of sensory information processing and its plasticity by sensory experience 19,20. Previous studies showed that apomorphine injection increases proto-oncogene transcription in the striatum and the barrel cortex 21, suggesting that dopaminergic receptor activation can alter gene transcription in the somatosensory cortex. Surgical transection of the infraorbital nerve, disrupting the sensory flow from the periphery, results in elevated dopamine release in the barrel cortex 22, plausibly contributing to the experience-dependent reorganization of the cortex. Despite these observations, it is not yet known whether dopaminergic signaling in the barrel cortex is differentially altered upon sensory experience. Here we took advantage of the recently completed transcriptomic mapping of the barrel cortex 23 to study this question. After identifying the 187 genes in the dopaminergic signaling pathway (DSP), we addressed 1) whether transcription of the DSP is regulated across cortical layers in the absence of sensory deprivation, 2) does prolong (two-week long) sensory deprivation alter DSP in a cortical column and layer specific manner, 3) is there a competition between sensory experience and sensory deprivation in controlling DSP and 4) the topography of the experience-dependent changes in DSP signaling. The results showed that in the absence of whisker deprivation, DSP signaling is uniform and comparable across the supragranular and granular layers of the barrel cortex. Whisker deprivation systematically reduces DSP signaling across the laminae which dominate gene transcription even in the spared whiskers' cortical columns neighboring the deprived column. Experience-dependent changes in DSP signaling are specific topographic, albeit broad. These results are the first direct observation and systematic analysis of the dopaminergic signaling

pathway in any sensory cortices and argue that whisker deprivation controls neuronal activity beyond the sensorimotor axis in the brain.

### **Experimental Procedures**

All experiments were performed in accordance with the Animal Ethics Committee of the Radboud University in Nijmegen, the Netherlands. The experimental procedures, including sensory deprivation<sup>13,44,45</sup>, isolation of cortical columns and laminae<sup>24</sup>, RNA isolation, quality control, and data validation<sup>23</sup> were as described. The RNAseq data is available for download<sup>46</sup> and can be searched and visualized online at [barrelomics.science.ru.nl](http://barrelomics.science.ru.nl).

#### *Animals*

Wild-type female C57Bl6 mice (Charles River: Wilmington, Massachusetts, United States, stock number 000664; RRID:NCBITaxon\_10090) were used for the experiments described herein. Animals (N=8; 4 mice/group) were randomly assigned to control and whisker deprivation groups 12 days after birth (P12). Experience-dependent plasticity was induced by whisker deprivation. Bilateral plucking of their C-row whiskers was performed under isoflurane anesthesia starting from P12, and repeated as necessary. Control animals were not plucked but anesthetized and handled similarly (sham plucked).

### **Slice preparation and sample collection**

Slice preparation was performed as described<sup>24</sup> on P23-P24. In short, pups were anaesthetized using isoflurane and perfused with ice-cold carbogenated slicing medium (108 mM ChCl, 3 mM KCl, 26 mM NaHCO<sub>3</sub>, 1.25 mM NaH<sub>2</sub>PO<sub>4</sub>, 25 mM glucose, 1 mM CaCl<sub>2</sub>, 6 mM MgSO<sub>4</sub>, and 3 mM Na-pyruvate). Acute thalamocortical slices (thickness 400  $\mu$ m) from each hemisphere were prepared as described before<sup>12,13,24</sup>. Slices were incubated in carbogenated artificial cerebrospinal fluid (ACSF) (120 mM NaCl, 3.5 mM KCl, 10 mM glucose, 2.5 mM CaCl<sub>2</sub>, 1.3 mM MgSO<sub>4</sub>, 25 mM NaHCO<sub>3</sub>, and 1.25 mM NaH<sub>2</sub>PO<sub>4</sub>) at 37°C for 30 minutes. After which they were gradually returned to room temperature prior to sample collection.

Cortical columns, A through E, were incised before granular layers (Layer, L, 4) and supragranular layers (L2/3) were isolated while the tissue was continuously perfused with carbogenated ACSF in room temperature as described<sup>24</sup>. Samples from columns A/E and B/D, which respectively correspond to the second- and first-order spared whiskers, were pooled. Thus giving 8 tissue clusters across two groups of animals (See Figure 1). Immediately after dissection, samples were snap-frozen in liquid nitrogen and stored at -80°C until further use. All tools that came into direct contact with brain tissue were treated using RNaseZap (Thermo Fisher Scientific: Waltham, Massachusetts, United States, #AM9780) in order to

minimize RNase contamination.

#### *RNA isolation and quality control*

Details on the RNA sequencing was provided before <sup>25</sup>. In short, tissues were quickly dissolved in Qiazol (Qiagen: Hilden, Germany, #79306) before RNA isolation performed using the miRNeasy Mini kit (Qiagen: Hilden, Germany, #217004). After DNase (Thermo Fisher Scientific: Waltham, Massachusetts, United States, #EN0521) treatment the tissue samples were cleaned using the RNeasy MinElute kit (Qiagen: Hilden, Germany, #74204) and subsequently stored at  $-80^{\circ}\text{C}$  until further processing.

RNA sample integrity was determined using Agilent Tapestation (Agilent: Santa Clara, USA, High Sensitivity RNA Screentape, #5067-5581). All samples had an RNA integrity (RIN) value  $>7.1$ , range 7.1-8.8. To confirm cDNA production and to ensure that a large (~1000 bp) amplicon could be obtained from the samples reverse transcription polymerase chain reaction (RT-PCR) was performed. cDNA was produced using SuperScript II Reverse Transcriptase (Thermo Fisher Scientific: Waltham, Massachusetts, United States, #18064014) with random hexamer primers (Roche: Basel, Switzerland, #11034731001). The resulting cDNA was then added to a PCR reaction mix, including Jumpstart Ready Mix (Sigma P2893) and exon-exon junction-spanning CamKII primers (FW TCCAACATTGTACGCCTCCAT; RV TGTGTTGGTGCTGTCTCGGAAGAT). From all cDNA samples, a fragment of the expected size could be amplified, suggesting that the RNA samples contained pure RNA of sufficient integrity.

#### *RNA sequencing*

RNA sequencing was conducted at the Genomics Core Facility of the EMBL, Heidelberg, Germany (RRID:SCR\_004473) as detailed before <sup>25</sup>. In short, the cDNA library was generated using the non-stranded NEBNext Ultra RNA Library Preparation Kit for Illumina (NEB: Ipswich, Massachusetts, United States, #E7530) via oligo-dT bead selection of mRNA. 13–14 PCR cycles were performed for library enrichment. Pooled libraries were sequenced on the Illumina: NextSeq 500 instrument (Illumina: San Diego, California, United States of America) (RRID:SCR\_014983) in a 75-bp paired-end mode using high-output flow cells. The data is available for download <sup>46</sup> and can be explored online at [barrelomics.science.ru.nl](http://barrelomics.science.ru.nl)

#### *Data validation and quality control*

Sequencing read quality was assessed using FastQC (Babraham Bioinformatics: Babraham, England; RRID:SCR\_014583), the results of which were merged using MultiQC (RRID:SCR\_014982) as detailed in <sup>25</sup>. Per base quality (phred) scores ranged from 34.80 to

35.15, indicating a base call accuracy better than >99.9% . Reads were mapped to the mm10 reference genome using STAR (RRID:SCR\_005622), which uniquely mapped between 39-59 million reads.

The library preparation required a PCR enrichment step which might lead to overestimation of observed transcripts. Analysis of the read density, using Seqmonk (Babraham Bioinformatics: Babraham, England; RRID:SCR\_001913), showed that a positive relation between read density and duplication levels and argued that the origin of read duplication is biological rather than technical.

#### *Analysis of gene expression*

To identify the genes in the dopaminergic signaling pathway (DSP), we performed a Mouse Genome Informatics gene ontology search at [http://www.informatics.jax.org/vocab/gene\\_ontology/](http://www.informatics.jax.org/vocab/gene_ontology/). DSP genes and their functional annotations are provided in Supplemental Table 1. The differential transcription analysis across experimental groups for the DSP genes was performed using transcript counts in MATLAB with custom written routines. Laminar analysis of the transcription was performed within each column across granular and supragranular layers. Within laminae analyses were performed across independent cortical columns. Statistical comparisons between groups were performed with two sample Kolmogorov-Smirnov test, ANOVA or paired t-test as noted. Hierarchical clustering of the expression data was performed using the *clustergram* function in MATLAB after normalizing the data within laminae across whisker deprivation conditions. See Figure legends for specific data handling procedures.

### **Results**

To address whether dopaminergic signaling pathway undergoes experience-dependent regulation here we studied the transcriptome in the mouse primary somatosensory cortex in a columnar and laminar resolution. Animals were divided into two groups, Control vs Whisker Deprived (Figure 1A). Whisker deprived mice received bilateral C-row deprivation for two weeks; Control animals received sham plucking (see Experimental Procedures for details).

**Figure 1. Genes in the Dopaminergic signaling pathway transcribe at comparable rates across layers in control animals.** (A) The sensory deprivation protocol (N=4 mice/group). (B) Thalamocortical slices of the barrel cortex were prepared from each hemisphere. (C) Cortical columns and layers of interest were isolated as described before<sup>24</sup> prior to RNA sequencing. (D) Genes in the dopaminergic signaling pathway (DSP, see Supplemental Table 1) were identified via Mouse Genome Informatics gene ontology search. The transcription rate of DSP genes was comparable across layers ( $p=0.54$ ; Kolmogorov-Smirnov test). Inset: Average number of transcript per gene (N=187) in DSP across granular (L4) and supragranular (L2/3) layers. (E) Comparison of gene transcription across layers. Each dot represents a gene in the DSP. Gene transcription did not significantly vary across layers (linear regression,  $R^2_{\text{adjusted}} = 0.96$ ,  $p=0.76$ , t-test). (F) Comparison of gene transcription by function across layers (see Supplemental Table 1 for functional annotations for each gene). None of the pairwise comparisons across layers within functional gene-clusters were significant ( $0.24 < p < 0.97$ , t-test). RNAseq data, read alignments (BAM files), and raw read counts as determined by STAR aligner can be found online <http://dx.doi.org/10.5524/100296>. Detailed descriptions of the data acquisition, processing, quality control, and validation can be found at<sup>25</sup>.

### *Transcription of the genes in Dopaminergic Signalling Pathway is not cortical laminae specific*

Comparison of the transcription across the 187 genes which contribute to dopaminergic signaling (see Supplemental Table 1) across cortical layers (L) 4 and L2/3 showed that gene transcription is not differentially regulated across laminae (Figure 1D). Because there are not any dopaminergic neurons in the neocortex, and dopaminergic axons originating from midbrain nuclei project throughout the cortical layers<sup>26</sup>, the observed molecular phenotype supports the existence of diffuse projections across cortical laminae in the juvenile mouse somatosensory cortex. Accordingly, pairwise comparison of the transcription for every

gene across the laminae showed that the transcriptional profile of DSP in the upper layers was predictive of one another (Figure 1E). Although gene transcription was differentially regulated across functional subgroups in the DSP, there was again no systematic change across laminae (Figure 1F).

#### *Experience-dependent regulation of DSP*

The transcriptome and proteome of the somatosensory cortex undergo experience-dependent regulation<sup>19,23,27</sup>. Given the extra cortical origin of dopamine, many of the genes in the DSP are located presynaptically. If their transcription in the somatosensory cortex is regulated by experience, it will shed light onto the consequences of sensory deprivation in structures that are not traditionally considered as nuclei that undergo experience-dependent plasticity.

To address the role of sensory experience in DSP regulation we compared the transcriptome of the DSP within laminae across Control and Whisker Deprived animals. DSP signaling in L4 (Figure 2A) and L2/3 (Figure 2B) were significantly modulated upon sensory deprivation as the lack of sensory input resulted in transcriptional suppression for DSP genes in the primary somatosensory cortex. The pairwise comparison of the gene transcription after normalization of the transcript count (Figure 2C) confirmed these observations and also showed that, except a handful of the genes, the direction and relative change in gene transcription are linearly correlated across the cortical laminae.

To distinguish the laminar expression pattern of the differentially transcribed genes we spatially and functionally classified the DSP (Figure 2D). The results showed that L2/3 is transcriptionally richer. There are relatively more transcripts across all functional classes that are differentially regulated by experience in a layer-specific manner. The relative degree of changes across the functional clusters can be visualized using cluster distance metrics (Figure 2E) which shows genes in the dopaminergic transport and update, dopamine secretion and synaptic transmission, dopaminergic neuron development, and dopamine metabolism are the principal functional classes regulated by sensory experience.

**Figure 2. Transcriptional regulation of the Dopaminergic signaling pathway upon whisker deprivation.** (A) Whisker deprivation suppresses gene transcription. Data from L4 of the C-columns from control (Control) and whisker deprived (Deprived) animals ( $p < 0.05$ ; Kolmogorov-Smirnov test). Inset: Average number of transcript per DSP gene across whisker deprivation conditions ( $F(1,186) = 12.1639$   $p < 0.001$ ; ANOVA). (B) Whisker-deprivation induced suppression in Dopaminergic gene transcription in L2/3 ( $p < 0.05$ ; Kolmogorov-Smirnov test). Inset: Average transcript count ( $F(1,186) = 7.5088$   $p < 0.001$ ; ANOVA). (C) Comparison of the relative change in gene transcription across cortical laminae. (D) Dopaminergic transcripts whose transcription is altered upon whisker deprivation grouped by simplified functional annotations. See Supplemental Tables 2 and 3 for the transcriptional data, results of the statistical analysis, and functional annotations based on MGI gene ontology. See Supplemental Table 4 for the laminar specificity of the transcriptional regulation for each differentially regulated gene upon whisker deprivation. Note that the intersection of the two rounded rectangles contains transcripts that are regulated by whisker deprivation both in L2/3 and L4. (E) Clustergram shows the relative distance between functional groups in terms of the relative change in transcription upon whisker deprivation. Data is normalized within laminae across whisker deprivation conditions. Whisker deprivation significantly altered the transcription of genes responsible for dopamine secretion and synaptic transmission (L2/3:  $p < 0.01$ ; L4:  $p = 0.01$ ), dopaminergic neuron development (L2/3:  $p < 0.005$ ; L4:  $p < 0.005$ ), dopamine metabolism (L2/3:  $p < 0.001$ ; L4:  $p < 0.001$ ), signal transduction in the dopaminergic pathway (L2/3:  $p < 0.01$ ; L4:  $p < 0.001$ ) and dopamine receptor binding (L2/3:  $p < 0.005$ ; L4:  $p < 0.005$ ; All comparisons: t-test).

### *The competition between sensory experience and sensory deprivation for DSP regulation*

Single row whisker deprivation results in synaptic competition in the barrel cortex. Although neurons in a given cortical column are primarily driven by a single whisker, contacts of the

first order neighboring whiskers are also represented by somatosensory neurons, due to broad, multi-whisker subthreshold representations<sup>20,28</sup>. Therefore in the deprived somatosensory cortex, neuronal activity in the first order spared whiskers' cortical columns is a product of the sensory input originating from their principal whisker as well as the adaptive (homeostatic) and long-term changes caused by sensory deprivation affecting their neighboring whisker<sup>12–15,29–33</sup>. To address whether DSP signaling is primarily driven by the sensory experience or deprivation, we compared the DSP transcriptome of the deprived (C) row column and the 1st order spared neighboring column. The transcription in L4 (Figure 3A) and L2/3 (Figure 3B) across the two groups were statistically comparable (Figure 3C). Although the transcriptional bias that we showed across the different functional subclasses in the DSP in the control animals was preserved (Figure 3D) only a small fraction of the transcripts (11/187) were differentially regulated across columns and layers (see Supplemental Tables 5-7 for differentially regulated transcripts). These results argue that there is a competition between sensory experience and deprivation for transcriptional regulation of the DSP, and sensory deprivation is the primary cause for the experience-dependent regulation in transcription.

**Figure 3. Competition between sensory experience and sensory deprivation in driving DSP signaling.** First order neighboring cortical columns (B/D) to the deprived C column are compared against the C column. (A-B) DSP signaling is not regulated by the sensory input in the 1st order spared whiskers' cortical columns neither in L4 ( $p=0.53$ ; Kolmogorov-Smirnov test) nor in L2/3 ( $p=0.99$ ; Kolmogorov-Smirnov test). Data from Control laminae are shown

in Figure 2 and are provided for herein for comparison. **(C)** Comparison of the relative change in gene transcription across cortical laminae per gene. L4:  $F(1,186)=0.8789$   $p=0.87$ ; ANOVA. L2/3:  $F(1,186)=0.2418$   $p=1$ ; ANOVA. **(D)** Comparison of gene transcription by function across layers (see Supplemental Table 1 for functional annotations for each gene). None of the pairwise comparisons across layers within functional gene-clusters were significant (paired t-test). **(E)** Comparison of the relative change in gene transcription across cortical laminae for each gene. See Supplemental Tables 5 and 6 for genes that are differentially transcribed in L4 and L2/3. **(F)** Clustergram shows the relative distance between functional groups in terms of the relative change in transcription across the deprived and the 1st order spared columns in animals that received whisker deprivation. Unlike the visualization in D, this analysis removes the co-variance within animal across cortical columns. Whisker deprivation significantly altered the transcription of genes responsible for dopamine receptor binding (L2/3:  $p<0.05$ ; L4:  $p<0.05$ ) and dopaminergic neuron development (L2/3:  $p<0.05$ ; L4:  $p<0.005$ ) both in L2/3 and L4 (All comparisons: t-test). See Supplemental Table 7 for the laminar distribution of transcripts that are differentially transcribed across the deprived and 1st order spared columns, organized by function.

### *The topography of the transcriptional regulation of the DSP*

Neuromodulatory projections into the somatosensory cortex are diffused and considered to lack the topography that exists in the ascending projections originating from the sensory periphery<sup>34,35</sup>. In the absence of topography, changes in the presynaptic dopaminergic drive might alter the neural function throughout the somatosensory cortex. Although this could be a powerful gain modulation mechanism, it could also impair behavior during partial sensory deprivation, like the single row deprivation protocol employed herein. Therefore, we compared the DSP transcriptome across the deprived and 2nd order spared cortical columns. Two cortical columns away from the deprived whisker, the DSP transcriptome fully recovered to the control levels (Figure 4A-C), and in L4 the transcription was up-regulated (Figure 4A,C). Pairwise comparison of the relative gene transcription across layers (Figure 4D) showed correlated changes across the laminae suggesting that DSP signaling is regulated topographically but independent from columnar identity. Accordingly, the majority of the upregulation in DSP transcription was observed in genes that are co-regulated both in L4 as well as L2/3 (Figure 4E).

**Figure 4. The topography of experience-dependent changes in DSP signaling.** Second order neighboring cortical columns (A/E) to the deprived C column are compared against the C column. **(A-B)** DSP signaling is transcriptionally potentiated in the second order spared column compared to the deprived column both in L4 and L2/3 ( $p=0.01$ ; Kolmogorov-Smirnov test). Data from Control laminae are shown in Figure 2 and are provided for herein for comparison. **(C)** Comparison of the relative change in gene transcription. Statistically significant comparisons are shown. Data from within animal across columns are compared using the paired t-test, data between animals is with ANOVA. **(D)** Comparison of the relative change in gene transcription across cortical laminae for each gene. See Supplemental Tables 8 and 9 for genes that are differentially transcribed in L4 and L2/3 across the deprived and second order spared columns. **(E)** Dopaminergic transcripts whose transcription is altered upon whisker deprivation grouped by simplified functional annotations. See Supplemental Table 10 for the laminar specificity of the transcriptional regulation for each differentially regulated gene upon whisker deprivation. Note that the intersection of the two rounded rectangles contains transcripts that are regulated by whisker deprivation both in L2/3 and L4.

## Discussion

Here we studied the gene transcription involved with dopaminergic signaling and showed that experience powerfully regulates the DSP transcription in the granular and supragranular layers of the cortex. The changes observed are driven by sensory deprivation as the DSP transcriptome of the 1st order spared whiskers' cortical columns is statistically indistinguishable from the deprived cortical columns'. Partial sensory deprivation does not

alter the transcription of the genes in DSP as cortical columns two order away from the deprived whisker have DSP transcriptome generally comparable to control animals.

Experience and layer dependent regulation of dopaminergic gene transcription contributes to complementary aspects of the pre and postsynaptic signaling. Genes whose transcription is down-regulated exclusively in L4 upon sensory deprivation (Agtr2, Alk, Arrb2, Flot1 and Cxcl12) are primarily involved in the regulation of extracellular dopamine availability and uptake. Agtr2 is responsible for encoding the angiotensin receptor 2, whose signaling is inhibited by dopamine at least in the striatum and substantia nigra <sup>36</sup>. As angiotensin receptor activation reduces dopaminergic uptake and increases dopamine availability <sup>37</sup>, its transcriptional downregulation by sensory deprivation is likely to reduce dopamine availability in L4. Arrb2 and Flot1 might compensate for the reduction in the dopaminergic drive, given their role in the internalization of dopaminergic receptors <sup>38</sup>, and localization and reverse transport of dopamine <sup>39</sup>, respectively. Cxcl12, on the other hand, encodes the SDF-1 protein that activates the nigrostriatal dopaminergic pathway via GPCR, increases the action potential frequency and induces burst firing of DA neurons <sup>40</sup>. SDF-1 also positively regulates voltage-dependent channels, potassium currents, and neurotransmitter release via calcium dependent mechanisms <sup>41</sup>. Therefore lack of sensory experience inhibits the dopaminergic signaling, localization and transport presynaptically in the principal thalamocortical recipient cortical layer.

Experience-dependent changes in dopaminergic signaling in L2/3 primarily contribute to the homeostasis of (postsynaptic) cellular and network excitability. The balance of neurotransmitters is crucial in order to maintain the homeostasis. Depending on the dopamine-glutamate ratio, Dlg4 controls D1R trafficking at the postsynaptic density <sup>42</sup>. This gene encodes a kinase family, membrane-associated guanylate kinase (MAGUK), critical for co-clustering of NMDA receptors, potassium channels and dopaminergic receptors <sup>43</sup>. Recruitment of D1R to the membrane is likely to be reduced upon sensory deprivation since the down-regulation of Cav2 transcription reduces Caveolin-2 availability <sup>44</sup>, which is required for synaptic localization of D1R <sup>45</sup>.

Transcriptional suppression of Gabbr1, the gene encoding GABA-B receptor, upon sensory deprivation functionally contributes to the homeostatic changes in GABA release, which depends on complex interactions between NMDAR and D1R <sup>46,47</sup>. Dopamine-dependent regulation of inhibitory drive is also subunit dependent <sup>48</sup>, as activation of Dopamine receptor subunit 4 inhibits GABA release via blockage of L-type  $\text{Ca}^{2+}$  channels <sup>49</sup>. The dopaminergic gating of cellular inhibition might also involve other surface receptors. For example, the cannabinoid receptor 1 (CB1), encoded by the gene Cnr1, has been associated with the homeostatic regulation of dopaminergic release through the control of inhibitory GABAergic

synapses in the PFC <sup>50</sup>. The activation of CB1, which is widely expressed in brain regions projecting to the NAc, leads to the inhibition of excitatory glutamatergic synapses, not only in the NAc <sup>51</sup> but also in the VTA, through interaction with D2R <sup>52</sup>. Experience-dependent downregulation of *Cnr1* might, therefore, correlate with increased excitatory (glutamatergic) drive, as D1R transport to the postsynaptic density (due to *Dlg4* suppression) and GABA-B availability are reduced (after down-regulation of *Gabbr1*) upon sensory deprivation, plausibly increasing the cellular excitability.

Experience-dependent dopaminergic regulation of other neurotransmitters' signaling and availability necessarily involves metabolic control of neurotransmitter synthesis and turnover. In L2/3, the sensory deprivation reduces the transcription of *Comt* and *Tor1a*, which control dopamine metabolization and contribute to dopamine clearance <sup>53,54</sup>. *Dbh* encodes dopamine beta-hydroxylase, an enzyme that has been associated with the D2 receptor activation, and converts dopamine into norepinephrine <sup>55</sup>. Considering that the transcription of *Chrn2*, which encodes a cholinergic nicotinic receptor <sup>56</sup>, is upon sensory deprivation, activity dependent changes in dopaminergic signaling might also have regulatory control over other neuromodulators.

Among the genes commonly found to be down-regulated after sensory deprivation in both L2/3 and L4, most of them are associated with receptor trafficking (*Dtnbp1*, *Flna*, *Gna11*, *Gna13*, *Gnaq*, *Gnas*), membrane localization (*Nat81*, *Nsf*, *Palm*, *Vps35*) and the metabolic control of neurotransmitter synthesis and turnover (*Dtnbp1*, *Maoa*). Thus sensory experience regulates dopaminergic signaling also in a cortical layer independent manner.

## Supplemental Materials

**Supplemental Table 1: List of genes associated with the dopaminergic signaling pathway**

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:2443582</i>	Abat	4-aminobutyrate aminotransferase	positive regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:2443582</i>	Abat	4-aminobutyrate aminotransferase	negative regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:99673</i>	Adcy5	adenylate cyclase 5	adenylate cyclase-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:99673</i>	Adcy5	adenylate cyclase 5	adenylate cyclase-inhibiting dopamine receptor signaling pathway	Signal transduction
<i>MGI:87917</i>	Adcy6	adenylate cyclase 6	dopamine receptor signaling pathway	Signal transduction
<i>MGI:99402</i>	Adora2a	adenosine A2a receptor	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:87937</i>	Adrb1	Adrenergic receptor, beta 1	dopamine binding	Dopamine binding
<i>MGI:87938</i>	Adrb2	Adrenergic receptor, beta 2	dopamine binding	Dopamine binding
<i>MGI:87964</i>	Agtr1a	angiotensin II receptor, type 1a	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:87964</i>	Agtr1a	angiotensin II receptor, type 1a	D1 dopamine receptor binding	Dopamine receptor binding
<i>MGI:87966</i>	Agtr2	angiotensin II receptor, type 2	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:103305</i>	Alk	anaplastic lymphoma kinase	regulation of dopamine receptor signaling pathway	Signal transduction
<i>MGI:99474</i>	Arrb2	arrestin, beta 2	D1 dopamine receptor binding	Dopamine receptor binding
<i>MGI:99474</i>	Arrb2	arrestin, beta 2	positive regulation of synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:88096</i>	Atf4	activating transcription factor 4	cellular response to dopamine	Signal transduction
<i>MGI:88107</i>	Atp1a3	ATPase, Na <sup>+</sup> /K <sup>+</sup> transporting, alpha 3 polypeptide	D1 dopamine receptor binding	Dopamine receptor binding

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:99400</i>	Atp7a	ATPase, Cu <sup>++</sup> transporting, alpha polypeptide	dopamine metabolic process	Dopamine metabolism
<i>MGI:1915816</i>	Caly	calcyon neuron-specific vesicular protein	dopamine receptor signaling pathway	Signal transduction
<i>MGI:107571</i>	Cav2	caveolin 2	D1 dopamine receptor binding	Dopamine receptor binding
<i>MGI:107571</i>	Cav2	caveolin 2	positive regulation of dopamine receptor signaling pathway	Signal transduction
<i>MGI:101765</i>	Cdk5	cyclin-dependent kinase 5	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:3606576</i>	Cdnf	cerebral dopamine neurotrophic factor	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1858236</i>	Celsr3	cadherin, EGF LAG seven-pass G-type receptor 3	dopaminergic neuron axon guidance	Dopaminergic neuron development
<i>MGI:109248</i>	Chrm5	cholinergic receptor, muscarinic 5	dopamine transport	Dopamine transport & uptake
<i>MGI:87888</i>	Chrna4	cholinergic receptor, nicotinic, alpha polypeptide 4	positive regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:87888</i>	Chrna4	cholinergic receptor, nicotinic, alpha polypeptide 4	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:106213</i>	Chrna6	cholinergic receptor, nicotinic, alpha polypeptide 6	positive regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:106213</i>	Chrna6	cholinergic receptor, nicotinic, alpha polypeptide 6	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:99779</i>	Chrna7	cholinergic receptor, nicotinic, alpha polypeptide 7	regulation of synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:87891</i>	Chrn2	cholinergic receptor, nicotinic, beta polypeptide 2 (neuronal)	regulation of dopamine metabolic process	Dopamine metabolism

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:87891</i>	Chrb2	cholinergic receptor, nicotinic, beta polypeptide 2 (neuronal)	positive regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:87891</i>	Chrb2	cholinergic receptor, nicotinic, beta polypeptide 2 (neuronal)	positive regulation of synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:87891</i>	Chrb2	cholinergic receptor, nicotinic, beta polypeptide 2 (neuronal)	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:87891</i>	Chrb2	cholinergic receptor, nicotinic, beta polypeptide 2 (neuronal)	regulation of synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:88414</i>	ckr	chakragati	negative regulation of dopamine receptor signaling pathway	Signal transduction
<i>MGI:2146607</i>	Clic6	chloride intracellular channel 6	D2 dopamine receptor binding	Dopamine receptor binding
<i>MGI:2146607</i>	Clic6	chloride intracellular channel 6	D3 dopamine receptor binding	Dopamine receptor binding
<i>MGI:2146607</i>	Clic6	chloride intracellular channel 6	D4 dopamine receptor binding	Dopamine receptor binding
<i>MGI:104615</i>	Cnr1	cannabinoid receptor 1 (brain)	negative regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:2183572</i>	Cntnap4	contactin associated protein-like 4	regulation of synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:88470</i>	Comt	catechol-O- methyltransferase	dopamine catabolic process	Dopamine metabolism
<i>MGI:88470</i>	Comt	catechol-O- methyltransferase	dopamine metabolic process	Dopamine metabolism
<i>MGI:88470</i>	Comt	catechol-O- methyltransferase	negative regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:88496</i>	Crh	corticotropin releasing hormone	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:88497</i>	Crhbp	corticotropin releasing hormone binding protein	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:1355272</i>	Csnk1d	casein kinase 1, delta	positive regulation of Wnt-mediated midbrain dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:88276</i>	Ctnnb1	catenin (cadherin associated protein), beta 1	midbrain dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:103556</i>	Cxcl12	chemokine (C-X-C motif) ligand 12	positive regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:103556</i>	Cxcl12	chemokine (C-X-C motif) ligand 12	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1929474</i>	Cyp2d22	cytochrome P450, family 2, subfamily d, polypeptide 22	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:1929474</i>	Cyp2d22	cytochrome P450, family 2, subfamily d, polypeptide 22	dopamine metabolic process	Dopamine metabolism
<i>MGI:94859</i>	Dao	D-amino acid oxidase	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:94861</i>	Das	dopamine agonist sensitivity	dopamine receptor signaling pathway	Signal transduction
<i>MGI:94864</i>	Dbh	dopamine beta hydroxylase	dopamine beta-monoxygenase activity	Dopamine metabolism
<i>MGI:94864</i>	Dbh	dopamine beta hydroxylase	dopamine catabolic process	Dopamine metabolism
<i>MGI:94876</i>	Ddc	dopa decarboxylase	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:1329040</i>	Dkk1	dickkopf WNT signaling pathway inhibitor 1	positive regulation of midbrain dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1277959</i>	Dlg4	discs large MAGUK scaffold protein 4	D1 dopamine receptor binding	Dopamine receptor binding
<i>MGI:2653629</i>	Dmrta2	doublesex and mab-3 related transcription factor like family A2	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1921580</i>	Dnajc14	DnaJ heat shock protein family (Hsp40) member C14	dopamine receptor binding	Dopamine receptor binding
<i>MGI:107384</i>	Dnm1	dynamamin 1	D2 dopamine receptor binding	Dopamine receptor binding
<i>MGI:109547</i>	Dnm2	dynamamin 2	D2 dopamine receptor binding	Dopamine receptor binding

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:109547</i>	Dnm2	dynamain 2	cellular response to dopamine	Signal transduction
<i>MGI:99578</i>	Drd1	dopamine receptor D1	dopamine transport	Dopamine transport & uptake
<i>MGI:99578</i>	Drd1	dopamine receptor D1	regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:99578</i>	Drd1	dopamine receptor D1	D3 dopamine receptor binding	Dopamine receptor binding
<i>MGI:99578</i>	Drd1	dopamine receptor D1	dopamine neurotransmitter receptor activity	Dopamine receptor binding
<i>MGI:99578</i>	Drd1	dopamine receptor D1	dopamine neurotransmitter receptor activity, coupled via Gs	Dopamine receptor binding
<i>MGI:99578</i>	Drd1	dopamine receptor D1	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:99578</i>	Drd1	dopamine receptor D1	adenylate cyclase-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:99578</i>	Drd1	dopamine receptor D1	cellular response to dopamine	Signal transduction
<i>MGI:99578</i>	Drd1	dopamine receptor D1	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:94924</i>	Drd2	dopamine receptor D2	dopamine metabolic process	Dopamine metabolism
<i>MGI:94924</i>	Drd2	dopamine receptor D2	dopamine neurotransmitter receptor activity	Dopamine receptor binding
<i>MGI:94924</i>	Drd2	dopamine receptor D2	dopamine neurotransmitter receptor activity, coupled via Gi/Go	Dopamine receptor binding
<i>MGI:94924</i>	Drd2	dopamine receptor D2	negative regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:94924</i>	Drd2	dopamine receptor D2	positive regulation of dopamine uptake involved in synaptic transmission	Dopamine transport & uptake
<i>MGI:94924</i>	Drd2	dopamine receptor D2	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:94924</i>	Drd2	dopamine receptor D2	regulation of dopamine uptake involved in synaptic transmission	Dopamine transport & uptake

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:94924</i>	Drd2	dopamine receptor D2	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:94924</i>	Drd2	dopamine receptor D2	adenylate cyclase- inhibiting dopamine receptor signaling pathway	Signal transduction
<i>MGI:94924</i>	Drd2	dopamine receptor D2	negative regulation of dopamine receptor signaling pathway	Signal transduction
<i>MGI:94924</i>	Drd2	dopamine receptor D2	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:94925</i>	Drd3	dopamine receptor D3	D1 dopamine receptor binding	Dopamine receptor binding
<i>MGI:94925</i>	Drd3	dopamine receptor D3	dopamine neurotransmitter receptor activity	Dopamine receptor binding
<i>MGI:94925</i>	Drd3	dopamine receptor D3	dopamine neurotransmitter receptor activity, coupled via Gi/Go	Dopamine receptor binding
<i>MGI:94925</i>	Drd3	dopamine receptor D3	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:94925</i>	Drd3	dopamine receptor D3	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:94925</i>	Drd3	dopamine receptor D3	adenylate cyclase- activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:94925</i>	Drd3	dopamine receptor D3	adenylate cyclase- inhibiting dopamine receptor signaling pathway	Signal transduction

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:94926</i>	Drd4	dopamine receptor D4	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:94926</i>	Drd4	dopamine receptor D4	adenylate cyclase- inhibiting dopamine receptor signaling pathway	Signal transduction
<i>MGI:94927</i>	Drd5	dopamine receptor D5	dopamine neurotransmitter receptor activity	Dopamine receptor binding
<i>MGI:94927</i>	Drd5	dopamine receptor D5	dopamine neurotransmitter receptor activity, coupled via Gs	Dopamine receptor binding
<i>MGI:94927</i>	Drd5	dopamine receptor D5	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:94927</i>	Drd5	dopamine receptor D5	adenylate cyclase- activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:94927</i>	Drd5	dopamine receptor D5	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:2137586</i>	Dtnbp1	dystrobrevin binding protein 1	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:2137586</i>	Dtnbp1	dystrobrevin binding protein 1	regulation of dopamine receptor signaling pathway	Signal transduction
<i>MGI:108100</i>	Dvl3	dishevelled segment polarity protein 3	Wnt signaling pathway involved in midbrain dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:95389</i>	En1	engrailed 1	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:95390</i>	En2	engrailed 2	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:102805</i>	Entpd1	ectonucleoside triphosphate diphosphohydrolase 1	negative regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:109169</i>	Epas1	endothelial PAS domain protein 1	positive regulation of dopamine biosynthetic process	Dopamine metabolism
<i>MGI:99604</i>	Fgf8	fibroblast growth factor 8	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:95556</i>	Flna	filamin, alpha	adenylate cyclase- inhibiting dopamine receptor signaling pathway	Signal transduction

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:1100500</i>	Flot1	flotillin 1	positive regulation of synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:1347476</i>	Foxa2	forkhead box A2	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:108476</i>	Fzd3	frizzled class receptor 3	dopaminergic neuron axon guidance	Dopaminergic neuron development
<i>MGI:1860139</i>	Gabbr1	gamma-aminobutyric acid (GABA) B receptor, 1	negative regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:14390</i>	Gabpa	GA repeat binding protein, alpha	cellular response to dopamine	Signal transduction
<i>MGI:95675</i>	Gch1	GTP cyclohydrolase 1	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:107430</i>	Gdnf	glial cell line derived neurotrophic factor	regulation of dopamine uptake involved in synaptic transmission	Dopamine transport & uptake
<i>MGI:95766</i>	Gna11	guanine nucleotide binding protein, alpha 11	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:95767</i>	Gna12	guanine nucleotide binding protein, alpha 12	D5 dopamine receptor binding	Dopamine receptor binding
<i>MGI:95768</i>	Gna13	guanine nucleotide binding protein, alpha 13	D5 dopamine receptor binding	Dopamine receptor binding
<i>MGI:95769</i>	Gna14	guanine nucleotide binding protein, alpha 14	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:95770</i>	Gna15	guanine nucleotide binding protein, alpha 15	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:95773</i>	Gnai3	guanine nucleotide binding protein (G protein), alpha inhibiting 3	dopamine receptor signaling pathway	Signal transduction
<i>MGI:95774</i>	Gnal	guanine nucleotide binding protein, alpha stimulating, olfactory type	adenylate cyclase-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:95775</i>	Gnao1	guanine nucleotide binding protein, alpha O	dopamine receptor signaling pathway	Signal transduction

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:95776</i>	Gnaq	guanine nucleotide binding protein, alpha q polypeptide	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:95777</i>	Gnas	GNAS (guanine nucleotide binding protein, alpha stimulating) complex locus	D1 dopamine receptor binding	Dopamine receptor binding
<i>MGI:95777</i>	Gnas	GNAS (guanine nucleotide binding protein, alpha stimulating) complex locus	adenylate cyclase-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:101848</i>	Gnb5	guanine nucleotide binding protein (G protein), beta 5	dopamine receptor signaling pathway	Signal transduction
<i>MGI:107193</i>	Gpr143	G protein-coupled receptor 143	dopamine binding	Dopamine binding
<i>MGI:338346</i>	Gpr21	G protein-coupled receptor 21	dopamine neurotransmitter receptor activity, coupled via Gs	Dopamine receptor binding
<i>MGI:1313297</i>	Gpr37	G protein-coupled receptor 37	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:1313297</i>	Gpr37	G-protein coupled receptor 37	positive regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:620246</i>	Gpr52	G protein-coupled receptor 52	dopamine neurotransmitter receptor activity, coupled via Gs	Dopamine receptor binding
<i>MGI:95820</i>	Grin2a	glutamate receptor, ionotropic, NMDA2B (epsilon 1)	dopamine metabolic process	Dopamine metabolism
<i>MGI:95821</i>	Grin2b	glutamate receptor, ionotropic, NMDA2B (epsilon 2)	D2 dopamine receptor binding	Dopamine receptor binding
<i>MGI:87941</i>	Grk3	G protein-coupled receptor kinase 3	D1 dopamine receptor binding	Dopamine receptor binding
<i>MGI:1861437</i>	Gsk3b	glycogen synthase kinase 3 beta	negative regulation of dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:106918</i>	Hif1a	hypoxia inducible factor 1, alpha subunit	dopaminergic neuron differentiation	Dopaminergic neuron development

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:96217</i>	Hprt	hypoxanthine guanine phosphoribosyl transferase	dopamine metabolic process	Dopamine metabolism
<i>MGI:96217</i>	Hprt	hypoxanthine guanine phosphoribosyl transferase	positive regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:96273</i>	Htr1a	5-hydroxytryptamine (serotonin) receptor 1A	regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:96274</i>	Htr1b	5-hydroxytryptamine (serotonin) receptor 1B	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:109521</i>	Htr2a	5-hydroxytryptamine (serotonin) receptor 2A	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:96281</i>	Htr2c	5-hydroxytryptamine (serotonin) receptor 2C	negative regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:1196627</i>	Htr6	5-hydroxytryptamine (serotonin) receptor 6	positive regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:99841</i>	Htr7	5-hydroxytryptamine (serotonin) receptor 7	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:96067</i>	Htt	huntingtin	dopamine receptor signaling pathway	Signal transduction
<i>MGI:96659</i>	Kcna2	potassium voltage-gated channel, shaker-related subfamily, member 2	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:1926803</i>	Kcnq4	potassium voltage-gated channel, subfamily Q, member 4	negative regulation of synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:2153049</i>	Klf16	kruppel-like factor 16	dopamine receptor signaling pathway	Signal transduction
<i>MGI:1888519</i>	Lmx1a	LIM homeobox transcription factor 1 alpha	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1888519</i>	Lmx1a	LIM homeobox transcription factor 1 alpha	midbrain dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1888519</i>	Lmx1a	LIM homeobox transcription factor 1 alpha	positive regulation of Wnt-mediated midbrain dopaminergic neuron differentiation	Dopaminergic neuron development

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:1100513</i>	Lmx1b	LIM homeobox transcription factor 1 beta	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1298218</i>	Lrp6	low density lipoprotein receptor-related protein 6	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1913975</i>	Lrrk2	leucine-rich repeat kinase 2	cellular response to dopamine	Signal transduction
<i>MGI:1913975</i>	Lrrk2	leucine-rich repeat kinase 2	positive regulation of dopamine receptor signaling pathway	Signal transduction
<i>MGI:1913975</i>	Lrrk2	leucine-rich repeat kinase 2	regulation of dopamine receptor signaling pathway	Signal transduction
<i>MGI:1922090</i>	Manf	mesencephalic astrocyte-derived neurotrophic factor	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:96915</i>	Maoa	monoamine oxidase A	dopamine catabolic process	Dopamine metabolism
<i>MGI:1346858</i>	Mapk1	mitogen-activated protein kinase 1	cellular response to dopamine	Signal transduction
<i>MGI:2652894</i>	Mapk15	mitogen-activated protein kinase 15	dopamine uptake	Dopamine transport & uptake
<i>MGI:1346859</i>	Mapk3	mitogen-activated protein kinase 3	cellular response to dopamine	Signal transduction
<i>MGI:96916</i>	Moab	monoamine oxidase B	positive regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:1921582</i>	Moxd1	monooxygenase, DBH-like 1	dopamine beta-monooxygenase activity	Dopamine metabolism
<i>MGI:1921582</i>	Moxd1	monooxygenase, DBH-like 1	dopamine catabolic process	Dopamine metabolism
<i>MGI:2388042</i>	Moxd2	monooxygenase, DBH-like 2	dopamine beta-monooxygenase activity	Dopamine metabolism
<i>MGI:2388042</i>	Moxd2	monooxygenase, DBH-like 2	dopamine catabolic process	Dopamine metabolism
<i>MGI:2447776</i>	Nat8l	N-acetyltransferase 8-like	positive regulation of dopamine uptake involved in synaptic transmission	Dopamine transport & uptake
<i>MGI:3038234</i>	nm3	neurological mutant 3	dopamine metabolic process	Dopamine metabolism
<i>MGI:97371</i>	Npr1	natriuretic peptide receptor 1	dopamine metabolic process	Dopamine metabolism

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:108418</i>	Npy2r	neuropeptide Y receptor Y2	positive regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:1352456</i>	Nr4a2	nuclear receptor subfamily 4, group A, member 2	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:1352456</i>	Nr4a2	nuclear receptor subfamily 4, group A, member 2	dopamine metabolic process	Dopamine metabolism
<i>MGI:1352456</i>	Nr4a2	nuclear receptor subfamily 4, group A, member 2	regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:1352456</i>	Nr4a2	nuclear receptor subfamily 4, group A, member 2	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:104560</i>	Nsf	N-ethylmaleimide sensitive fusion protein	D1 dopamine receptor binding	Dopamine receptor binding
<i>MGI:10949</i>	Nsg1	neuron specific gene family member 1	dopamine receptor signaling pathway	Signal transduction
<i>MGI:1202070</i>	Nsg2	neuron specific gene family member 2	dopamine receptor signaling pathway	Signal transduction
<i>MGI:3030935</i>	Olfr1101	olfactory receptor 1101	dopamine neurotransmitter receptor activity, coupled via Gi/Go	Dopamine receptor binding
<i>MGI:3030935</i>	Olfr1101	olfactory receptor 1101	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:3030935</i>	Olfr1101	olfactory receptor 1101	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:3030935</i>	Olfr1101	olfactory receptor 1101	adenylate cyclase-inhibiting dopamine receptor signaling pathway	Signal transduction
<i>MGI:3030935</i>	Olfr1101	olfactory receptor 1101	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:2659178</i>	Olfr150	olfactory receptor 150	dopamine neurotransmitter receptor activity, coupled via Gi/Go	Dopamine receptor binding
<i>MGI:2659178</i>	Olfr150	olfactory receptor 150	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:2659178</i>	Olfr150	olfactory receptor 150	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:2659178</i>	Olfr150	olfactory receptor 150	adenylate cyclase-inhibiting dopamine receptor signaling pathway	Signal transduction

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:2659178</i>	Olfr150	olfactory receptor 150	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:3030109</i>	Olfr275	olfactory receptor 275	dopamine neurotransmitter receptor activity, coupled via Gi/Go	Dopamine receptor binding
<i>MGI:3030109</i>	Olfr275	olfactory receptor 275	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:3030109</i>	Olfr275	olfactory receptor 275	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:3030109</i>	Olfr275	olfactory receptor 275	adenylate cyclase- inhibiting dopamine receptor signaling pathway	Signal transduction
<i>MGI:3030109</i>	Olfr275	olfactory receptor 275	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:3030517</i>	Olfr683	olfactory receptor 683	dopamine neurotransmitter receptor activity, coupled via Gi/Go	Dopamine receptor binding
<i>MGI:3030517</i>	Olfr683	olfactory receptor 683	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:3030517</i>	Olfr683	olfactory receptor 683	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:3030517</i>	Olfr683	olfactory receptor 683	adenylate cyclase- inhibiting dopamine receptor signaling pathway	Signal transduction

<i>MGI:96285</i>	Slc6a4	solute carrier family 6 (neurotransmitter transporter, serotonin), member 4	dopamine uptake involved in synaptic transmission	Dopamine transport & uptake
<i>MGI:96285</i>	Slc6a4	solute carrier family 6 (neurotransmitter transporter, serotonin), member 4	dopamine: sodium symporter activity	Dopamine transport & uptake
<i>MGI:96285</i>	Slc6a4	solute carrier family 6 (neurotransmitter transporter, serotonin), member 4	negative regulation of synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:96285</i>	Slc6a4	solute carrier family 6 (neurotransmitter transporter, serotonin), member 4	negative regulation of synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:1349482</i>	Slc9a3r1	solute carrier family 9 (sodium/hydrogen exchanger), member 3 regulator 1	adenylate cyclase-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:1349482</i>	Slc9a3r1	solute carrier family 9 (sodium/hydrogen exchanger), member 3 regulator 1	phospholipase C-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:1927578</i>	Smpd3	sphingomyelin phosphodiesterase 3, neutral	dopamine uptake	Dopamine transport & uptake
<i>MGI:1277151</i>	Snca	synuclein, alpha	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:1277151</i>	Snca	synuclein, alpha	dopamine metabolic process	Dopamine metabolism
<i>MGI:1277151</i>	Snca	synuclein, alpha	negative regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:1277151</i>	Snca	synuclein, alpha	negative regulation of dopamine uptake involved in synaptic transmission	Dopamine transport & uptake
<i>MGI:1277151</i>	Snca	synuclein, alpha	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:1277151</i>	Snca	synuclein, alpha	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:1915097</i>	Sncaip	synuclein, alpha interacting protein (synphilin)	dopamine metabolic process	Dopamine metabolism
<i>MGI:1889011</i>	Sncb	synuclein, beta	dopamine metabolic process	Dopamine metabolism
<i>MGI:1298397</i>	Sncg	synuclein, gamma	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:103078</i>	Spr	sepiapterin reductase	dopamine metabolic process	Dopamine metabolism
<i>MGI:102896</i>	Sult1a1	sulfotransferase family 1A, phenol-preferring, member 1	aryl sulfotransferase activity	Dopamine metabolism
<i>MGI:2136282</i>	Sult1b1	sulfotransferase family 1B, member 1	aryl sulfotransferase activity	Dopamine metabolism

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:102928</i>	Sult1c1	sulfotransferase family, cytosolic, 1C, member 1	aryl sulfotransferase activity	Dopamine metabolism
<i>MGI:1926341</i>	Sult1d1	sulfotransferase family 1D, member 1	aryl sulfotransferase activity	Dopamine metabolism
<i>MGI:99667</i>	Syt1	synaptotagmin I	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:101759</i>	Syt4	synaptotagmin IV	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:1859545</i>	Syt7	synaptotagmin VII	regulation of dopamine secretion	Dopamine secretion & synaptic transmission
<i>MGI:2148258</i>	Taar1	trace amine-associated receptor 1	adenylate cyclase-activating dopamine receptor signaling pathway	Signal transduction
<i>MGI:892968</i>	Tacr3	tachykinin receptor 3	regulation of dopamine metabolic process	Dopamine metabolism
<i>MGI:98726</i>	Tgfb2	transforming growth factor, beta 2	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:98735</i>	Th	tyrosine hydroxylase	dopamine biosynthetic process	Dopamine metabolism
<i>MGI:98735</i>	Th	tyrosine hydroxylase	synaptic transmission, dopaminergic	Dopamine secretion & synaptic transmission
<i>MGI:103306</i>	Tiam1	T cell lymphoma invasion and metastasis 1	regulation of dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1353568</i>	Tor1a	torsin family 1, member A (torsin A)	regulation of dopamine uptake involved in synaptic transmission	Dopamine transport & uptake
<i>MGI:98849</i>	Tshr	thyroid stimulating hormone receptor	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:2135272</i>	Vangl2	VANGL planar cell polarity 2	dopaminergic neuron axon guidance	Dopaminergic neuron development
<i>MGI:103178</i>	Vegfa	vascular endothelial growth factor A	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:108037</i>	Vegfd	vascular endothelial growth factor D	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:1890467</i>	Vps35	VPS35 retromer complex component	positive regulation of dopamine biosynthetic process	Dopamine metabolism
<i>MGI:1890467</i>	Vps35	VPS35 retromer complex component	D1 dopamine receptor binding	Dopamine receptor binding

<i>MGI Gene/ Marker ID</i>	<i>Gene symbol</i>	<i>Gene name</i>	<i>Annotated function</i>	<i>GoSlim annotation</i>
<i>MGI:1890467</i>	Vps35	VPS35 retromer complex component	positive regulation of dopamine receptor signaling pathway	Signal transduction
<i>MGI:98953</i>	Wnt1	wingless-type MMTV integration site family, member 1	astrocyte-dopaminergic neuron signaling	Dopaminergic neuron development
<i>MGI:98953</i>	Wnt1	wingless-type MMTV integration site family, member 1	canonical Wnt signaling pathway involved in midbrain dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:98953</i>	Wnt1	wingless-type MMTV integration site family, member 1	dopaminergic neuron differentiation	Dopaminergic neuron development
<i>MGI:98953</i>	Wnt1	wingless-type MMTV integration site family, member 1	midbrain dopaminergic neuron differentiation	Dopaminergic neuron development

# Chapter 5

**Sparsification of sensory representations  
by dopamine**

Sensory perception is an orchestrated outcome of the central circuits of the brain. It requires integration of the bottom-up information from the periphery with the top-down, often neuromodulatory, information originating elsewhere in the brain. Recent studies in the whisker system showed that monoamines, particularly serotonin, performs gain-modulation for adaptive control of active sensing. Here we show that another monoamine, dopamine, powerfully controls sensory processing and neural representation of the sensory information in the somatosensory cortex. Specifically, we demonstrate that pharmacological activation of the D1-like dopaminergic receptors (D1R) in the somatosensory cortex from freely-behaving animals results in faster integration of the sensory information. The mechanism underlying this behavioral improvement might be explained by the bidirectional control of neuronal excitability by D1R activation. Intracellular whole-cell recordings before, during and after the activation of the D1R showed that receptor activation results in firing rate suppression in excitatory neurons and facilitation in inhibitory neurons. Intracellularly, this cell-type dependent modulation is regulated by sodium channels and accompanied by the correlated changes in calcium dynamics both in dendrites and soma. Taken together, the results indicate that the D1 signaling in the somatosensory cortex contributes to sensory information processing, improves integration of tactile evidence to reach a perceptual decision and performs cell-type specific gain modulation to enhance inhibitory neurons' contribution to sensory coding in the neocortex.

The perception of the environment is dictated by sensory processing, which depends on the sensory representations in the brain. Dopamine is one of the neurotransmitters mediating this process, heterogeneously affecting neuronal responses both in sensory <sup>1</sup> and motor <sup>2</sup> systems. This is an active process, as evidenced by the dopaminergic regulation of spike-timing-dependent plasticity in structures related to the sensory processing <sup>3,4</sup>. Dopamine is also important for decision-making, reward and memory processing, thus its regulation of the stimulus representation in sensory circuits might have over-arching consequences for the processing and representation of sensory stimuli based on prior experiences.

A subregion of the primary somatosensory cortex (S1), named barrel cortex, is responsible for the processing of sensory inputs coming from the whiskers, and constitute one of the major sensory systems in rodents. As layer 2/3 (L2/3) of the S1 integrates neuronal inputs coming from surrounding cortical columns via horizontal connections, long-range neocortical inputs via L1 and information (including neuromodulatory) originating elsewhere in the brain, it is suitable for studying top-down and bottom-up processing of cortical sensory information. Monoamines are known to interfere with the development of this cortical neurons, modulate the balance between excitation and inhibition, and shape the contribution of these neurons to tactile processing <sup>5-7</sup>. Although they seem to have no influence in the thalamocortical projections that pattern the barrel formations, they are necessary for the maturation of layer (L) 4 and L2/3 of the barrel cortex <sup>8</sup>. Moreover, S1 sends excitatory inputs to the Substantia Nigra (SN), reducing the latency for responding to stimuli predicted to be rewarded <sup>9</sup>. This indicates that the dopaminergic and the somatosensory systems are functionally coupled throughout life.

Dopamine receptors are differentially present in all cortical layers, L1 through L6: D1-like receptors are generally more expressed than D2, in both pyramidal and interneurons <sup>10</sup>. The D1 receptor activates the cAMP/PKA cascade resulting in the activation of many downstream protein targets, such as AKAP-15 <sup>11</sup> and DARPP-32 <sup>12</sup>, which phosphorylates/dephosphorylates voltage-gated sodium channels ( $Na_v$ ), thus modulating sodium conductance in the cortical neurons (also see Chapter 1). Because  $Na_v$  channels are responsible for establishing the spike threshold for action potential generation, it is not surprising that in hippocampus <sup>13</sup>, midbrain <sup>14</sup> and basal ganglia <sup>15</sup>, dopamine is shown to increase the spike threshold and duration, decreasing the postsynaptic excitability via the modulation of sodium and calcium channels. This dopamine-mediated increase in spike threshold is also observed in the striatum, where it mediates inhibition of hyperpolarizing potential, and controls spike latency <sup>16</sup>.

Despite the indirect evidence concerning the role of dopamine for sensory processing, and the empirical findings on the dopaminergic control of neuronal excitability and spike timing,

whether dopaminergic signaling controls sensory processing in the somatosensory cortex is not yet known. Therefore, in this study, we studied the contribution of the dopaminergic receptors for neuronal and behavioral information processing. The results showed that dopamine controls excitability in a cell-type specific manner. While D1R activation hyperpolarizes spike-threshold and increases firing rate in inhibitory neurons, it inhibits stimulus-evoked spiking in the excitatory neurons. As a result, information transferred between cortical neurons are shaped bidirectionally by the activation of the D1Rs. The behavioral consequence of this modulatory control by D1Rs is the facilitation of sensory integration, as animals require substantially less sensory information to successfully locate tactile targets. This cell-type specific control of excitability by dopaminergic receptor activation is likely to act as a gain-modulator, increasing the signal-to-noise during goal-directed behavior.

### **Materials and Methods**

The physiology of the dopaminergic activation across the different receptor types was investigated through pharmacological manipulation by dopaminergic agonists (D1: SKF38393, D2: Quinpirole) and antagonists (D1: SCH23390, D2: Sulpiride) both in cell cultures and brain slices using intracellular recordings and calcium imaging. All animal procedures were approved by the Radboud University Animal Experiment Committee.

#### *Experiments in neocortical cell cultures*

Cultures of dissociated cortical neurons were prepared from postnatal day 0 mice on C57BL/6J background. The mother was sacrificed by cervical dislocation, pups by decapitation, before their brains were rapidly removed. Brains were put on ice-cold Hank's balanced salts solution (HBBS; pH 7.3) comprising 10% HBSS without magnesium or calcium (Gibco Life Technologies; Catalog number (Cat.nr.): 14175129), 100 U/ml penicillin-streptomycin (Thermo Fisher Scientific; Cat.nr. 15140122) and 500  $\mu$ M GlutaMAX<sup>TM</sup> (Thermo Fisher Scientific; Cat.nr. 35050061). Neocortex was removed bilaterally and incubated in HBSS with 5% trypsin solution (Gibco Life Technologies; Cat.nr. 15090046). The solution was removed, and the cells were dissociated using a fire-polished Pasteur's pipette. Dissociated neurons were plated onto 25 mm coverslips, coated with 1% (weight/volume) poly-L-lysine (Sigma-Aldrich; Cat.nr. 25988-63-0), with a density of  $1.6 \times 10^5$ /coverslip. Cultures were maintained at 37°C in culture medium comprising neurobasal medium (Thermo Fisher Scientific; Catalog number: 21103049) and carbonated (95%O<sub>2</sub>/ 5% CO<sub>2</sub>), supplemented with 2% B27 Supplement (Thermo Fisher Scientific; Cat.nr. 17504044) and 500  $\mu$ M GlutaMAX<sup>TM</sup> (Thermo Fisher Scientific; Cat.nr. 35050061). On day 5, the culture medium was replaced with medium without glutamate. Half of the medium was changed twice per week.

Virally expressed GCaMP6s<sup>17</sup> under the CaMK2 promoter was used for visualization of the intracellular calcium dynamics. Viral packaging was adapted from<sup>18–20</sup>. In short, a suspension of 37.5 µg pRV1 (AAV2) (6.25 µg/plate), 37.5 µg pH21 (AAV1) (6.25 µg/plate), 125 µg pFΔ6 (Ad Helper) (25 µg/plate), 62.5 µg GCaMP6 (12.5 µg/plate), 2 ml CaCl<sub>2</sub> (2.5 M; Merck; Cat. nr. 1023820500) and 12 ml of ddH<sub>2</sub>O were slowly added (5 ml/15 cm plate) to HEK293 cells (density: 800.000 cells/plate) as plates were gently swirled. Viral transfection was confirmed 48 hours later with the Eclipse TS100 light microscope (Nikon) coupled with the epi-fluorescence illuminator Nikon Intensilight C-HGFIE and viral particles were purified with heparin (GE Healthcare; Cat.nr. 170406013). Concentration of the virus was checked with qPCR (fwd ITR primer, 5'-GGAACCCCTAGTGATGGAGTT-3', and rev ITR primer, 5'-CGGCCTCAGTGAGCGA-3'), as in<sup>21</sup>. 2 µl of the virus was transferred to dissociated neuronal cell cultures (plate diameter: 25 mm) on day 2 of the culture (DIV2). For these experiments, two batches of the virus with titers of  $4.92 \times 10^{12}$  and  $1.86 \times 10^{12}$  were used. Transfected neurons were stored in the cell incubator at 37°C until the fluorescence was visible.

Neurons were visualized using LED illumination (Cooled, pE-100) and a camera (Q-imaging, Model number: EXI-BLU-R-F-M-14-C, CA) coupled to a light microscope (Nikon, FN1) placed on an active vibration isolation table (Table Stable; TS-150). Data was acquired full field at 10 fps in MicroManager (<https://micro-manager.org/>) at 14-bit with a readout time of 30 MHz. Data acquisition was triggered using a custom Arduino interface, coupling whole-cell recording (see below) software Patchmaster (HEKA) with MicroManager, camera, and the excitation light source. Electrical recordings, electrical stimulation and calcium imaging were time aligned with clock signals generated in the Patchmaster.

Cell cultures were used 9–15 days after plating, i.e. 7–13 days after viral transfection. Pyramidal neurons were visually selected according to their somatic shape and dendritic morphology. The culture plate was continuously perfused with Ringer's solutions (in mM): 10 HEPES (Sigma-Aldrich, Cat.nr. 7364459); 150.1 NaCl; 5 KCl; 1.5 CaCl<sub>2</sub>·2H<sub>2</sub>O; 1 MgCl<sub>2</sub>·6H<sub>2</sub>O; 10 Glucose·H<sub>2</sub>O; pH 7.4 adjusted with NaOH (all last chemicals are from Merck, Cat.nrs., respectively are: 7647145, 7447407, 100350408, 1058330250, 14431437).

Patch pipette electrodes with a resistance of 5–9 MΩ were pulled from borosilicate glass (Multi Channel Systems; Cat.nr. 300034) using a horizontal puller (Sutter instrument CO. Model P-2000). Intra-pipette solution included (in mM): 5 KCl (Merck, Cat.nr. 7447407); 130 K-Gluconate; 1.5 MgCl<sub>2</sub>·6H<sub>2</sub>O; 0.4 Na<sub>3</sub>GTP; 4 Na<sub>2</sub>ATP; 10 HEPES; 10 Na-phosphocreatine; 0.6 EGTA (Sigma-Aldrich, Cat.nrs., respectively are: 299274, 1058330250, G877, A26209, 7364459, P7936, 67425). pH was set to 7.22 using KOH (1 M; Merck; Cat.nr. 5033). A

chlorided silver wire was used to create electrical continuity between the intra-pipette solution and head-stage, connected to EPC 9 amplifier (HEKA).

Somatic whole-cell configuration was achieved as described before <sup>22</sup>. Current-clamp recordings were performed using step-and-hold pulses, 500 ms in duration. 10 steps of 40 pA current were delivered in every train, and each train was repeated three times. Sweep duration was set to 7 sec. Resting membrane potential was clamped at -70 mV. Evoked calcium dynamics were visualized as described above after binning (x2) with an exposure duration of 100 ms.

#### *Electrophysiology of layer 2/3 pyramidal neurons in slices*

Recordings from 47 cells coming from 34 Pval-cre and SSt-cre mice between 11 and 54 weeks (15 male, 19 female) were used in this study. Acute slices of the barrel cortex were prepared as described before <sup>23</sup>. In short, mice were anesthetized with Isoflurane (10 ml/mouse) and the depth of the anesthesia was assessed by pinch withdrawal before perfusion in the cooled solution containing (in mM): 108 choline chloride, 3 KCl, 26 NaHCO<sub>3</sub>, 1.25 NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O, 25 Glucose·H<sub>2</sub>O, 1 CaCl<sub>2</sub>·2H<sub>2</sub>O, 6 MgSO<sub>4</sub>·7H<sub>2</sub>O, 3 Na-pyruvate. Animals were decapitated for brain extraction and sliced in the same solution. Brain slices were then transferred to a chamber with ACSF (in mM): 1200 NaCl, 35 KCl, 100 Glucose·H<sub>2</sub>O, 25 CaCl<sub>2</sub>·2H<sub>2</sub>O, 13 MgSO<sub>4</sub>·7H<sub>2</sub>O, 250 NaHCO<sub>3</sub>, 12.5 NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O, carbonated with 95% O<sub>2</sub>/5% CO<sub>2</sub>. The coronal slices were then kept oxygenated at 37°C for 30 minutes and then 30 minutes in room temperature before the whole-cell recordings. The slice was then placed in a chamber under the microscope and was continuously oxygenated and perfused with ACSF. The barrel cortex was localized using the 20x lens and the pyramidal cells were patched with a 40x lens.

For the electrophysiological recordings, conventional current-clamp and voltage-clamp <sup>24,25</sup> configurations were used. All data were collected while somatic membrane potential was clamped at -70 mV. Two types (step-and-hold and frozen noise) current-clamp protocols were used as described in Chapter 2. In the voltage-clamp mode, there were 4 types of protocols used. First, a sawtooth voltage sweep from -70 mV to +70 mV in 100 ms five times was performed. This was repeated twice. Subsequently, the same five sawtooth waves were performed in 50 ms and in 10 ms in cycle duration, corresponding to stimulus frequencies of 10, 20, 100 Hz, respectively. Finally, the membrane voltage was clamped at -70 mV while applying 14 increasing steps of 10 mV for 250 ms, with a 20 s interval. Collectively these protocols allowed me to address the ionic bases of dopaminergic modulation of neuronal activity.

During these experiments select pharmacological agents, such as SKF38393 (D1 agonist,

1  $\mu\text{M}$ ), Quinpirole (D2 agonist, 10  $\mu\text{M}$ ), Dopamine (50  $\mu\text{M}$ ), SCH23390 (D1 antagonist, 1  $\mu\text{M}$ ), Sulpiride (D2 antagonist, 10  $\mu\text{M}$ ), plus additional tetrodotoxin (TTX, 10  $\mu\text{M}$ ), EGTA ( $\text{Ca}^{2+}$  channels blocker (1, 2 and 20  $\mu\text{M}$ )),  $\text{NiCl}_2$  ( $\text{Ca}^{2+}$  channels blocker, 1  $\mu\text{M}$ ),  $\text{CdCl}_2$  (1  $\mu\text{M}$ ), targeting specific ion channels were also administered to causally address the mechanisms involved with dopaminergic regulation of the neuronal excitability.

Following data acquisition, we used a custom program in MATLAB to systematically extract the characteristics from the neurons measured. Cell-type classification was performed based on K-means clustering using the maximum firing rate and the mean spike half-width. Comparisons were made with ANOVA repeated measures, Student's t-test and post-hoc analysis with Bonferroni statistical test. Non-parametric comparisons were made with Kruskal-Wallis test and Kolmogorov-Smirnov test.

### *Behavioral experiments*

Adults animals were trained on the spontaneous gap-crossing task as described before<sup>6,18,26–29</sup>. In short, animals were placed on an elevated platform (so called “home” platform) and were allowed to explore their environment in darkness, without light in the visible spectrum to the mammalian eye. A second elevated platform placed with a variable distance to the home platform served as a tactile target (see Figure 4A). A high-speed camera placed above the experimental chamber acquired animal navigation at a rate of 400 frame-per-second (spatial resolution 40 microm/pixel) and this videographic data were analyzed offline for quantification of sensorimotor exploration.

After initial training, the distance between the home and target platforms were set so that the animals could contact the target platform using only their whiskers. Once animals reached this, so-called whisker-distance trials, D1 agonist (SKF38393 in Ringer's solution, 0.25  $\mu\text{g}/\text{mouse}$ , volume: 200 nl) or vehicle (Ringer's solution, 200 nl) injections were performed via a cannula implanted in the brain prior to the start of training. The order of the injections was randomized (N=30 trials/condition). The data analysis was performed using custom written routines in MATLAB as described before<sup>6,18,26,27</sup>.

## **Results**

Sensory information is encoded by regulation of rate and timing of action potentials<sup>30</sup>. To address whether dopaminergic signaling can modulate generation of action potential, we performed whole-cell recordings in acute slices of the adult mouse barrel cortex (Figure 1). The results showed that D1 receptor activation resulted in reduction in spiking frequency (n=16, ANOVA repeated measures,  $p < 0.001$ ) although the effect size was small ( $\eta^2 = 0.077$ ) during sustained somatic current injections. D2 activation in pyramidal neurons increases

the spike frequency ( $n=7$ , ANOVA repeated measures,  $p=0.031$ ; Figure 1C). In fast-spiking neurons, activation of D1 receptors increases spiking (D1: ( $n=16$ , ANOVA repeated measures,  $p<0.001$ ,  $\eta^2=0.254$ ). Preliminary experiments ( $N=3$ ) showed that the D2 agonist Quinpirole tends to increase the action potential count in fast-spiking neurons (ANOVA repeated measures,  $p<0.001$ ,  $\eta^2=0.586$ ).

**Figure 1. D1 and D2 agonists selectively modulate information transfer in a cell type specific manner.** (A) Action potential traces of a representative pyramidal neuron under Control, D1 agonist (SKF 38393, 1  $\mu$ M, in purple) and D2 agonist (Quinpirole, 10  $\mu$ M, in light blue, bottom row) treatments. (B) Representative interneuron under Control, D1 agonist (SKF 38393, 1  $\mu$ M, purple) and (Quinpirole, 10  $\mu$ M, in light blue, bottom row) treatments. (C) Comparison of D1 and D2 agonist treatments in Regular (red) and Fast Spiking (blue) neurons. Dashed lines show the drug effect in the spike frequency. Minimal effect is observed in regular spiking neurons, while fast spiking neurons show significant increase after both D1 ( $n=16$ , Student's  $t$  test,  $p<0.001$ , ANOVA repeated measures,  $p<0.001$ ,  $\eta^2=0.254$ ) and D2 ( $n=3$ , Student's  $t$  test,  $p<0.001$ , ANOVA repeated measures,  $p<0.001$ ,  $\eta^2=0.586$ ) agonists treatments. (D-E) D1 and D2 agonists reduced the change in Df/F in neocortical cell cultures in both active spines (D) and somas (E). The change in fluorescence (Df/F) was normalized to the maximum change per stimulus. See main text for statistical comparisons. ago = agonist; Rec = recovery.

Dopaminergic regulation of the action potential generation is thought to be mediated through T-type calcium channels<sup>31–33</sup>. Therefore, we quantified the changes in intracellular calcium

using genetically encoded calcium indicator, GCaMP6s in dissociated neuronal cultures from the neocortex. Although increasing stimulus intensity was not accompanied by a systematic change in the amplitude of the calcium signals in spines (Figure 1D), D1 agonist (SKF38393, 1  $\mu$ M) decreased the calcium transients significantly in all stimulus levels ( $n=191$ , ANOVA repeated measures,  $p=0.01$ , Bonferroni,  $p<0.001$ ). Similar to D1, D2 agonist (Quinpirole, 10  $\mu$ M) decreased evoked calcium transients of active spines significantly and the long-lasting effect remained after the drug administration was ceased (Recovery condition,  $p<0.001$ ).

Although the average calcium transients were reduced, the number of active spines and soma varied depending on the dopaminergic receptor activated. The number of active spines increased by 4 folds during D2 agonist administration (Control  $n = 12$ , D2  $n=48$ ), and slowly reduced post-administration (D2:  $n=35$ ). However, D1R agonist reduced the number of active spines both during and post administration (Control:  $n=191$ , D1:  $n=55$ , Recovery:  $n=41$ ; Figure 1D). The calcium dynamics in soma generally followed the observations in dendritic spines with the exception that D1R activation resulted in uniform reduction of calcium transient across all stimulus conditions, while D2R activation was most effective in lower stimulus intensities (Figure 1E; All comparisons ANOVA for repeated measures  $p<0.05$ ). These observations argue that dopaminergic signaling mediated regulation of calcium might be cell-type dependent.

Although dopaminergic regulation of calcium dynamics contributes to the regulation of cellular excitability, observed changes in spiking dynamics might rather involve voltage-gated sodium ( $\text{Na}_v$ ) channels. As reviewed in Chapter 1, in several subcortical structures, dopamine has been shown to regulate  $\text{Na}_v$  conductance. We thus quantified the inward currents in whole-cell voltage clamp configuration (Figure 2). Both cell classes displayed prominent inward currents which were suppressed after tetrodotoxin administration (Figure 2A-B). The statistics of the  $\text{Na}_v$  transients were altered upon D1R activation (Figure 2C). The peak and the total amplitude of the transients were reduced upon D1R activation and the membrane potential at which  $\text{Na}_v$  opened was hyperpolarized (Figure 2C) when all experiments were considered together.

**Figure 2. D1 agonist reduces the amplitude of inward currents and affects timing in regular- and fast-spiking neurons.** (A) Voltage-clamp recordings of 100 ms triangular sweeps demonstrated that D1 agonist (SKF38393, 1  $\mu$ M, purple) reduces sodium currents amplitudes in fast-spiking neurons, as sodium blocker tetrodotoxin (TTX) removes the inward currents completely (black). (B) The same occurs in regular-spiking neurons, with a higher remission. (C) D1R agonist reduced the amplitude of the first current (Student's t-test,  $p=0.006$ ), starting voltage (Student's t-test,  $p=0.06$ ) and integral (Student's t-test,  $p=0.01$ ) of the inward currents, while tending to increase timing (Student's t-test,  $p=0.10$ ) when all experiments considered together. Splitting data across cell groups reduced the power in the statistical comparisons, thus the cell type specific grouping of the data does not imply cell type specific changes.

Considering that dopaminergic receptor activation results in the reduction of voltage-gated sodium channel conductance, dopamine might control intracellular information transfer as somatic postsynaptic potentials are translated to action potentials. To directly quantify the information transfer we utilized a recently developed information theoretic<sup>36,37</sup> approach that computes the mutual information between a bandwidth limited time-varying current injected into the soma (entitled “frozen noise”) with action potentials generated by the neuron (Figure 3A). Both regular-spiking (presumed excitatory) and fast-spiking (presumed inhibitory) neurons responded robustly to the somatic injection of “frozen noise” in control conditions and during drug administration (Figure 3B). D1R caused hyperpolarization of the action potential threshold in both classes of neurons across a large range of inter-spike intervals (Figure 3C) although fast-spiking neurons fired action potentials in more hyperpolarized membrane potentials (Figure 3D).

**Figure 3. D1R activation controls intracellular information transfer in a cell-type specific manner.** (A) Experimental protocol. To calculate the mutual information between current injected in soma (“frozen noise”) and the action potentials generated by the neuron, we computed synaptic inputs impinging on the postsynaptic neuron as an output of a 1000 neuron network (see <sup>36</sup> for details). The frozen noise was injected in soma in acute slices of the adult barrel cortex. (B) Example of response in regular-spiking (RS) and fast-spiking (FS) neurons, under *Control* (ACSF, gray) and *D1 agonist* (SKF38393, 1  $\mu$ M, purple) treatments. (C) Normalized spike count as a function of per interspike interval (ISI) and action potential (AP) threshold in RS and FS neurons before and during D1R activation. (D-E) Change in spike threshold (D) and firing rate, quantified as ISI (E), across drug conditions and cell types. All within cell type across drug conditions are statistically significant, Kruskal-Wallis test,  $p < 0.05$ . (F-G) Information content of action potentials. (F) Information plotted against the firing rate. (G) Change in information transfer across drug conditions in both cell classes. Both within cell type across drug condition comparisons are statistically significant, Kruskal-Wallis test,  $p < 0.05$ . (H) Change in information during D1R activation normalized to the change in firing rate across drug conditions. (I) Receiver-operating-characteristics of the spiking pattern. Hit: When the postsynaptic neuron fires action potential upon the upstate transition in the frozen noise; False alarm: When postsynaptic action potential is generated in the absence of an upstate.

Similar to our observations made during sustained somatic depolarization with a step-and-hold current pulse, frozen noise injection showed that D1R activation results in firing rate modulation; while the firing rate of regular-spiking neurons was reduced, fast-spiking neurons spiked at higher frequencies (Figure 3E). The change in the firing rate was directly correlated with the degree of information transfer. In regularly spiking neurons D1R activation caused reduction of the information (Figure 3F, left) although inhibitory neurons carried more information in their action potentials (Figure 3F, right). Comparisons of the total information transferred within a cell-type before and during D1R agonist application supported the conclusion that D1R facilitates information processing in presumed inhibitory neurons, while reducing the information content of excitatory neurons (Figure 3G), effectively selectively gating inhibition. Considering that relative change in information content remained constant in respect to the normalized firing rate change (Figure 3H), this differential regulation of information processing by D1R is due to the firing rate modulation of D1R activation.

Change in intracellular information transfer might control barrel cortical neurons' ability to encode the sensory stimulus. We thus quantified receiver-operator-characteristic (ROC) curve for both cell classes before and during D1R stimulation. The results showed that D1R activation increases the sensory encoding in inhibitory neurons and reduced in excitatory neurons (Figure 3I).

The role of D1R in controlling action potential threshold, firing rate and the information transfer between neurons in the somatosensory cortex suggests that dopaminergic signaling ultimately modulates sensory processing in freely behaving animals. Therefore we trained animals on a tactile object localization task, called spontaneous gap-crossing task<sup>6,18,26–29</sup>. On this task animals locate a tactile target, an elevated platform, while standing on another platform located beyond a gap (Figure 4A). A camera located above the gap is used to observe animals and collect the sensory statistics of decision making.

To regulate the D1R activation during task execution, we implanted animals with a guide cannula and trained animals to criteria, i.e. two consecutive sessions with 5+ trials during which animals contacted the target only using their whiskers before successful object localization. After animals reached the criteria, animals received either D1 agonist (SKF38393) or vehicle (Ringer's solution) for 30 trials/drug condition. The animals did not receive any whisker deprivation during these experiments.

Post-hoc analysis of the whisker contacts<sup>38</sup> showed that D1R activation results in faster decision-making as the latency to cross after the first contact was twice as long after vehicle injection (Vehicle vs D1R agonist,  $911 \pm 214$  vs  $417 \pm 54$  ms (mean  $\pm$  sem), ANOVA,  $P < 0.05$ ; Figure 4B). The animals required significantly less sensory information to make their decision (Vehicle vs D1R agonist,  $931 \pm 115$  vs  $583 \pm 68$  ms (mean  $\pm$  sem), ANOVA,  $P < 0.05$ ; Figure

4D). Although both touch duration per whisker contact (Vehicle vs D1R agonist,  $17.3 \pm 0.32$  vs  $15.9 \pm 0.34$  ms (mean  $\pm$  sem), Kolmogorov-Smirnov Test,  $P < 0.05$ ; Figure 4E, left) and number of whiskers simultaneously in contact with the target (Vehicle vs D1R agonist,  $3.1 \pm 0.03$  vs  $2.9 \pm 0.04$  (mean  $\pm$  sem), Kolmogorov-Smirnov Test,  $P < 0.05$ ; Figure 4E, right) were significantly different, the primary contributor to the reduced sensory exploration was the reduced number of whisker contacts with the target (Vehicle vs D1R agonist,  $53.7 \pm 6.62$  vs  $36.6 \pm 3.7$  ms (mean  $\pm$  sem), ANOVA,  $P < 0.05$ ; Figure 4F). These results argue that D1R activation regulates integration of sensory information during tactile decision making.

**Figure 4. The consequences of D1R activation for tactile decision making.** (A) Gap-crossing paradigm. (B) Quantification of sensory exploration. (C) Latency to cross, described as the temporal difference between the very first whisker contact with the target platform and animal's nose crossing the target platform as the animal crosses the gap, jumps on the target. (D) Tactile evidence leading to successful target localization across groups. Tactile evidence is calculated as the total duration of whisker contacts with the target. Note that animals had all of their whiskers intact, thus the variable is an integral of all contacts with the target by any whisker. (E) Touch duration is calculated as described in B. Number of whisker that are in contact with the target platform is calculated by binning the data in the temporal domain (2.5 ms/bin). (F) Total number of contacts made onto the target prior to successful target localization.

## Discussion

Decision-making requires precise integration of information coming from various brain systems, demanding selection of relevant sensory inputs and top-down control based on previous knowledge. Tactile information coming from the mouse whiskers during an adequate number of contacts with the object will ultimately result in crossing the gap to explore another space. Here using intracellular recording, calcium imaging, behavioral recordings and pharmacological modulation of receptor activation, we show that dopamine is a potent regulator of cellular and behavioral information processing in the somatosensory cortex.

D1R activation in the somatosensory cortex functions as a top-down control mechanism, reducing the number of contacts required, hence improving performance and facilitating learning. The temporal precision of the neuronal signaling is imperative for sensory and movement constituents coordination by dopaminergic midbrain neurons during learning<sup>39</sup>. In the corticostriatal pathway, D1R activation shortly before pre- and postsynaptic paired stimulation converts LTD into LTP, needing a precise temporal window of maximum 2 seconds<sup>40</sup>. This dopamine-mediated spike-timing-dependent plasticity demonstrates the importance of this neurotransmitter for reinforcement learning<sup>40,41</sup>.

At the neuronal network scale, we found dopamine receptors coordinating excitation and inhibition of the somatosensory system in a cell-type-specific manner. Dopaminergic neuromodulation is known to suppress firing in cortical neurons (e.g.<sup>42</sup>). Nevertheless, the novelty of this study is to describe cell-type-specific modulation in L2/3 of the S1. Dopamine release and calcium signaling are intrinsically correlated, as (also) shown herein. Calcium stimulates dopamine release via potassium-dependent depolarization of neurons<sup>43</sup>. Dopaminergic activation of D4 also modulates the information transfer via calcium release after direct activation of IP<sub>3</sub><sup>44</sup>, independently from L-type Ca<sup>2+</sup> channels<sup>44</sup>.

Recent studies now argue for a compartmentalized effect of dopamine, which controls spine excitability by activation of T-type calcium (Ca<sup>2+</sup>) channels in the substantia nigra (SN)<sup>45</sup>. Neurons with a stronger expression of T-type Ca<sup>2+</sup> channels display higher responsiveness to excitatory inputs<sup>45</sup>. The information integration of sensory and motor cortices during whisking likewise arise from calcium activity in the dendrites<sup>46</sup>, sometimes intervening with the neuronal maturation and plasticity through LTD (for a review see<sup>47</sup>). Furthermore, dopaminergic neurons expressing Calbindin, a calcium binding protein, exhibit a delayed firing pattern during spontaneous activity<sup>48</sup>. Calcium dynamics dependent on L-type and T-type channels can also alter the direction of pre/postsynaptic plasticity if combined with GABAergic activation<sup>49</sup>. Because calcium signals follow sensory stimulation in a specialized subcellular level<sup>50</sup>, they complement the voltage response in action potentials and may represent multiple other features in the neuronal network, such as time, location, or contact.

Considering that dopamine is required for corticostriatal plasticity<sup>51,52</sup>, understanding the dopaminergic control of internal calcium release would be of use further for explaining memory and plasticity. Conclusively, this powerful influence linking calcium and dopamine circumscribes the firing rate and pattern.

Another possibility for explaining the cell-type-specific response to the dopaminergic drive is the location and engagement of voltage-dependent sodium and potassium channels, which are directly involved in determining the action potential threshold. Membrane configurations as a result of intrinsic properties or repetitive synaptic inputs play a role in firing rate of both cortical pyramidal and interneurons<sup>53</sup>. Sodium and calcium channels also act in the amplification of backpropagating spike trains in neocortical pyramidal neurons dendrites<sup>54</sup>, interfering with temporal coding. Moreover, in the mPFC, dopamine enhances excitatory inputs of local circuits of layer V, while blocking the influence of layer I inputs, confirming differential modulation of two subtypes of pyramidal cells, in this instance<sup>55</sup>.

Throughout modulation of calcium signaling, voltage-gated channels and spike-timing-dependent plasticity, dopamine presumably serve as a gain-modulator during sensory processing of tactile information and improves behavior execution. Overall, the cell-type-specific dopaminergic control of excitability enables an increase in signal-to-noise ratio during behavior, for performing a modulatory control of the signal through facilitating fast-spiking neurons information transfer while not affecting regular-spiking neurons in the same manner.

# Chapter 6

## Compartmental regulation of calcium by Corticosterone

It is estimated that ~90% of the world population suffers from high levels of stress during at least a period in their lifetime. Stress may give rise to major mental disorders such as anxiety, depression and mood disorders either as a contributing or a triggering factor. Cortisol is released from the adrenal cortex during stress. In humans, cortisol release is correlated with enhanced sensory, in particular tactile, processing. The mechanism by which cortisol alters sensation is not yet known. In rodents, it has been shown that corticosterone (Cort), a metabolite of cortisol, controls  $\text{Ca}^{2+}$  signaling in a region-specific manner. Specifically,  $\text{Ca}^{2+}$  currents, mediated by high-voltage activated (L-type)  $\text{Ca}^{2+}$  channels, are augmented in the hippocampal CA1 region and basolateral amygdala upon in vitro Cort administration through genomic mechanisms. However, Cort mediated intracellular  $\text{Ca}^{2+}$  homeostasis is not ubiquitous, which makes the critical examination of its local effects in sensory circuits crucial. In this chapter, this question is addressed following pharmacological interrogation of GR activation and calcium imaging in acute slices of the somatosensory cortex and in neocortical cell cultures. The results show that Cort modulates evoked calcium transients in soma but not in spines suggesting that Cort action is compartmentalized in individual neurons. These findings have far-reaching implications including adaptive gain modulation of sensory information during the integration of synaptic currents in soma which ultimately controls what information will be transmitted in synaptically coupled networks.

Stress is a physical reaction, plausibly originated from our evolutionary needs to defend ourselves or prevent damage to our body. Reaction to stress differs across individuals. A cue or a context can be interpreted as stressful by someone and still be neutral to another person. If, for example, one once had an accident crossing a street, this experience may trigger more alertness towards all related stimuli, let it be a car, bus, or a screeching sound. Therefore, sensory processing and perception can be regulated by stress, while stress might serve as an active filter for sensory processing.

When our body identifies a stressor, that is, any stimulus threatening the body's homeostasis <sup>1</sup>, two systems, i.e. the sympatho-adrenomedullary system and the hypothalamic-pituitary-adrenal (HPA) axis, are activated simultaneously <sup>2</sup>. The former rapidly releases epinephrine and norepinephrine (NE) by the adrenal medulla and the nerve terminals of the sympathetic nervous system <sup>3</sup>. The latter, upon the activation of the vagal nerve, indirectly increases the activity of noradrenergic neurons in the nucleus tractus solitarius and in the locus coeruleus <sup>4</sup>, and controls the glucocorticoid levels in the body <sup>5</sup>.

The activation of the sympatho-adrenomedullary system is widely considered to trigger the Fight-or-Flight response, increase alertness and attention <sup>6-8</sup>. The HPA-axis activation leads to the secretion of corticotropin-releasing hormone (CRH) and vasopressin (AVP) from the Paraventricular nucleus (PVN) <sup>9</sup>. These hormones reach the anterior pituitary through the portal vessel system, and stimulate the production of pro-opiomelanocortin (POMC). POMC, a precursor to the adrenocorticotrophic hormone (ACTH), promotes ACTH release which in turn enhances glucocorticoid release from the adrenal cortex <sup>9</sup>. High levels of glucocorticoid release induce a negative feedback control on the HPA axis <sup>5</sup>.

Corticosterone (Cort) and cortisol are the glucocorticoids known as “stress hormones”, the former predominant in rodents and the latter in humans <sup>2</sup>. They are synthesized in the adrenal cortex, *zona fasciculata*, a region that regulates many vital functions of the body including immunologic, metabolic and homeostatic functions <sup>2,5</sup>. Because of their lipophilic characteristic, they can cross the brain-blood barrier without any difficulty, being able to reach all cells in the brain, but they can only exert their effects on those cells that express their receptor <sup>1</sup>. During our circadian cycle, corticosteroids are released phasically, however when a stressor is present, there is an increase in their release <sup>2</sup>. In order to generate an effect in the brain, the glucocorticoids bind the mineralocorticoids (MR) and glucocorticoids (GR) receptors <sup>2</sup>. These are nuclear receptors <sup>10</sup> and regulate transcription <sup>1</sup>. The affinity of glucocorticoids is higher for MR, which are recruited even at low concentrations of Cort. GR has a tenfold lower affinity when compared to MR and is activated only when the levels of glucocorticoids are significantly (but often only transiently) elevated, e.g. after a stressful situation or at the high peak of the Cort cycle <sup>11</sup>.

Corticosteroids alter brain function through genomic and non-genomic mechanisms <sup>11</sup>. MR and GR are present in the cytoplasm before binding to their corticosteroid targets, and when the binding takes place, ligand-receptor complexes are translocated to the nucleus <sup>11</sup>. Corticosteroids, once they are in the nucleus, can alter gene transcription directly or indirectly via DNA binding or through interaction with transcriptional elements <sup>11</sup>. For instance, in rat CA1 pyramidal neurons, a brief application of Cort raises the amplitude of high-voltage activated sustained  $\text{Ca}^{2+}$  currents, primarily through a change in L-type  $\text{Ca}^{2+}$  currents <sup>12</sup>, which requires GR-mediated protein synthesis. However, Corticosteroid-mediated MR activation affects L-type  $\text{Ca}^{2+}$  channels densities in a dose-dependent manner <sup>13</sup>. P/Q-, N-, R- and T- types of  $\text{Ca}^{2+}$  channels are also associated with intracellular calcium modulation by increased levels of Cort <sup>14</sup>. The dose-dependent activation of GR or MR affects the synaptic transmission through distinct mechanisms. In the short term, the amplitude of the miniature excitatory postsynaptic currents (mEPSC) is increased although mEPSCs decay faster after corticosteroid application <sup>15</sup>. In the longer term, the membrane is depolarized via a transcription-dependent increase in intracellular calcium, which increases the amplitude of mEPSCs <sup>15</sup>. As both influx and efflux of  $\text{Ca}^{2+}$  are regulated by GRs it is not surprising that GRs potentially modulate neuronal communication and synaptic plasticity in a wide range of synaptic circuits <sup>11</sup>.

Given the highly non-linear compartmental dynamics of the calcium signaling in the neocortex <sup>16,17</sup>, Cort action in regulation of calcium signaling in the neocortex might be critical in shaping communication across the network. Therefore, in this study, I addressed the Cort action on calcium signaling using genetically encoded calcium indicators and inorganic dyes. The results showed that Cort regulates calcium dynamics in soma, but not dendrites, suggesting that Cort might alter cellular excitability, plausibly controlling spike timing in sensory neurons.

## Materials and Methods

### *Animals*

Eight weeks old male Sprague Dawley rats (Charles River Laboratories) were given *ad libitum* access to food and water and housed on a 12-hour light/dark cycle. They were anesthetized (Isoflurane) and perfused with iced and oxygenated (95%  $\text{O}_2$ /5%  $\text{CO}_2$ ) slicing medium (SM) containing, in mM: 10.8  $\text{CHCl}_3$ , 0.3  $\text{KCl}$ , 2.6  $\text{NaHCO}_3$ , 0.125  $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ , 2.5  $\text{Glucose} \cdot \text{H}_2\text{O}$ , 0.1  $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ , 0.6  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , 0.3  $\text{Na-Pyruvate}$ .

Cultures of dissociated cortical neurons were prepared from prenatal E18 Wistar rats. The mother was sacrificed by cervical dislocation, pups by decapitation, and pup brains were rapidly removed. All experimental procedures were approved by the Ethical Committee for

Animal Experimentation of Radboud University.

### *Experimental procedures*

Acute coronal sections (400  $\mu\text{m}$ ) of the barrel cortex were sliced in cold and carbonated SM. Sections were then incubated for 30 min in a chamber filled with carbonated (95/5%  $\text{O}_2/\text{CO}_2$ ) artificial cerebrospinal fluid (ACSF) containing, in mM: 120 NaCl, 3.5 KCl, 1.3  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , 2.5  $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ , 10 Glucose. $\text{H}_2\text{O}$ , 1.25  $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ , 25  $\text{NaHCO}_3$ ) at  $37^\circ\text{C}$  for 1 hour. The temperature was subsequently gradually reduced to room temperature and slices were transferred to a recording chamber where they were perfused continuously with oxygenated ACSF at the room temperature. Three injections of Fluo4AM were made in layer 2/3 of the barrel cortex where calcium dynamics were studied upon electrical stimulation of layer 4 using a bipolar electrode.

The protocol consisted of three repetitions of a voltage series between 0.5 - 4V delivered with an interstimulus interval of 20 sec, which was repeated a second time 30 minutes later. After that, each slice was perfused with one of the six pharmacological agents: ACSF containing 0.05% ethanol; 10  $\mu\text{M}$ , 100 nM, or 20 nM isoproterenol (ISO); 5  $\mu\text{M}$  NE; 1  $\mu\text{M}$  Cort; 10  $\mu\text{M}$  ISO with 100 nM Cort; or 10  $\mu\text{M}$  ISO with 0.05% ethanol for 20 min to regulate  $\alpha$ -1,  $\beta$ -2 and GR receptors. The stimulus protocol was repeated a third time after the pharmacological intervention and the bath solution was immediately changed back to ACSF to wash the agents off of the slice for 30 min. Finally, the stimulation protocol was repeated a fourth time. Data acquisition was performed using Q-imaging Exi blue camera controlled through Master-8 and micromanager.

Cell culture preparation: After animals were euthanized by decapitation on E18, brains were isolated and cooled ice-cold Hank's balanced salts solution (HBBS) containing 10% HBSS without Mg or Ca (Gibco/Invitrogen), 100 U/ml penicillin (LifeTechnologies), 100  $\mu\text{g}/\text{ml}$  streptomycin (LifeTechnologies), 500  $\mu\text{M}$  glutamine and 12.5  $\mu\text{M}$  glutamate (Sigma, pH 7.3). Cortices were removed and incubated in HBSS with 5% trypsin solution (Gibco/Invitrogen). The solution was removed, and the cells were dissociated using a fire-polished Pasteur's pipette.

Dissociated neurons were plated onto 24 mm coverslips, coated with 1% poly-D-lysine (Fisher Scientific), with a density of  $1.6 \cdot 10^5/\text{coverslip}$ . Cultures were maintained at  $37^\circ\text{C}$  in a humidified atmosphere (95%  $\text{O}_2$ /5%  $\text{CO}_2$ ) in a culture medium comprising neurobasal medium (Gibco/Invitrogen), supplemented with 2% B27 Supplement (Gibco/Invitrogen), 500  $\mu\text{M}$  glutamine and 12.5  $\mu\text{M}$  glutamate. After five days, the culture medium was replaced with the same medium but without glutamate. Half the medium was changed twice per week. Cultures were used for 13-17 days after plating. Calcium imaging in cultured neurons was

performed using GCaMP6s (see below). Neurons were virally transfected two days after the plating.

Prior to calcium imaging cells were incubated with Cort (100 nM, dissolved in 20  $\mu$ M Ethanol, N=10), Ethanol (EtOH, 20  $\mu$ M, Vehicle group, N=9) or Ringer's (Control group, N=10) solution for 20 min in room temperature protected in a light-tight environment. The plate was then washed with Ringers before it was placed under the microscope (Nikon FN-2SN) and kept perfused continuously with carbonated ACSF 2 mL per minute, at room temperature for one hour before imaging started. Evoked calcium transients were triggered using KCl (60 mM) puffs (1.6 mL/each for a total duration of 10 sec).

#### *Preparation of GCaMP6 and transfection*

AAV-HEK293 cells (ATTC, < p+25) were maintained in Culture Medium (DMEM supplemented with 10% FCS, 1 mM Na-Pyruvate and Pen/Strep). For GCaMP6s-AAV virus production, 48 hours prior transfection AAV-HEK293 cells were plated onto poly-L-Lysine-coated 15-cm cultures dishes and cultured until a confluence of ~80% was reached. For CaPO<sub>4</sub>-transfection, 37.5  $\mu$ g pRV1 (AAV2); 37.5  $\mu$ g pH21 (AAV1); 150  $\mu$ g pFdelta6 (Ad Helper), and 75  $\mu$ g pAAV-CaMKIIa-GCaMP6 plasmid DNA were mixed with 1.44 ml 2.5 M CaCl<sub>2</sub> and 12 ml of MQ water. Then, while mixing the solution, 13 ml of 2xHBS (280 mM NaCl, 50 mM HEPES, 1.42 mM Na<sub>2</sub>HPO<sub>4</sub>, pH 7.05) was added gradually. This mixture (5 ml/plate) was added to the plate and 16 hours later cells were supplied with fresh culture medium. Virus production continued 48-72 hours after transfection.

Viral particles were isolated from the cells essentially as previously described<sup>18</sup>. In short, cells were collected in warm PBS, lysed in Lysis buffer (150 mM NaCl, 20 mM Tris, pH 8.0) supplemented with 0.5% deoxycholate and 50 u/ml Benzonase. After clearing the lysate by centrifugation, AAV virus was isolated using a HiTrap heparin column (GE Healthcare, #17-0406-01) and afterward concentrated in PBS using Ultracel-100K centrifugal filter units (Amicon, #UFC810024). Batches #2 (physical titer: 4.92\*10<sup>12</sup> genomes/ml) and #4 (physical titer: 1.86\*10<sup>12</sup> genomes/ml) were used to transduce dissociated cortical neuronal cultures.

#### *Data analysis*

The data analysis was performed using in-house software written in MATLAB (MathWorks). The fractional change in fluorescence was calculated and normalized to the baseline illumination in single pixel resolution and data are represented as  $df/F=(f-F)/F$ , where  $f$  is evoked responses and  $F$  is the illumination prior to the onset of stimulus.

## Results

Here we addressed the role of corticosterone in controlling calcium dynamics in acute slices of the primary somatosensory cortex and in cultures of dissociated neocortical neurons. Epifluorescence imaging in acute slices allowed visualization of population dynamics (Figure 1), at the expense of spatial resolution, while imaging in dissociated cultures provided high resolution, compartmental analysis of the changes in calcium, using single-photon excitation (Figure 2).

**Figure 1. Visualization of population calcium dynamics in acute slices of the barrel cortex.** Calcium transients were detected using Fluo4 injected in three locations in layers (L) 2/3 of the barrel cortex, while electrical stimulation was delivered to the L4 using bipolar electrodes. (A) Three injection sites and magnitude of basal fluorescence amplitude in pseudo colors. Warmer colors represent higher fluorescence. A single image was acquired in the absence of electrical stimulation. (B) ROI (Region of Interest) identified by thresholding, in this example 60% of the global maximum fluorescence. (C) The intensity of the fluorescence over repetitive electrical stimulation. Increase in fluorescence intensity (calcium influx) is seen due to consecutive electrical stimulations. (D) Average of the fluorescence after three repetitions, across voltage steps of 0.5 V. (E) Average dF/F as a function of stimulus intensity. Incremental elevation in stimulation intensity led to an increase in dF/F, indicating more calcium influx. (F) There was small to no variation across the three repetitions of the experiment. Color code indicates the stimulus intensity (in V).

**Figure 2. Compartmental visualization of the calcium dynamics in slice cultures.** (A) Top: Raw GCaMP6s signal displayed as an intensity image. Bottom: Isolated and labeled soma after image segmentation. (B) Time course of the evoked response in identified soma in a single trial. The stimulus was delivered 20 sec into the trial. Data recorded at 10 fps. (C) Same as in B but data from identified spines. (D) Normalized change in fluorescence ( $df/F$ ) in active and inactive soma, classified statistically based on whether stimulus evoked significant response above background in a given soma, and spines (right).

#### *Acute application of Cort with ISO suppresses population calcium activity in S1*

As expected, neuronal excitability, as measured by evoked calcium signals, were increased in proportion to the stimulus intensity (Figure 3, 2-way-ANOVA,  $p < 0.001$ ,  $\eta^2 = 0.218$ ). However, the change in excitability calculated by the  $df/F$  was minimal across all conditions in acute cortical slices. The exception was the reduced excitability observed in Cort combined with ISO (Figure 3B, 2-way-ANOVA,  $p < 0.001$ ), but with a small effect size ( $\eta^2 = 0.036$ ).

The significant reduction was specific to stimuli above 3V (Student's *t* test,  $p < 0.001$ ), when compared to Control. The experiments with Ethanol-only treatment showed the lowest *df/F* values, while experiments with ISO (including combined with ethanol or combined with Cort) had the highest change in evoked calcium amplitude (Figure 3).

**Figure 3. Reduction in evoked calcium transients in the acute slices of the barrel cortex (Layer 2/3).** Each slice was studied prior to administration of pharmacological agents (*Control*), during the application (*Drug*) of norepinephrine (NE), isoproterenol (ISO), ethanol (EtOH), and corticosterone (Cort), and after reperfusion with ACSF (*Recovery*). (A) Data were normalized to the maximum *df/F* across stimuli. In all drug conditions the amplitude of evoked calcium transients increased in proportion to the stimulus intensity (ANOVA repeated measures,  $p < 0.001$ ). (B) Evoked calcium transients were reduced across all drug conditions compared to *Control*, but only significantly in acute treatment of Cort+ISO, above 3V stimuli (2-way-ANOVA,  $p < 0.001$ ,  $\eta^2 = 0.036$ , Bonferroni,  $p < 0.001$ ). No significant differences were found in any other experimental conditions in comparison to control. (C) This reduction in calcium transient was sustained for at least 50 min including during *recovery* (Cort+ISO in comparison to *Control*, Bonferroni,  $p < 0.001$ ). A tendency of reduction observed in ISO (ANOVA repeated measures,  $p = 0.04$ ) was not confirmed by post-hoc statistics in comparison to *Control* (Bonferroni,  $p = 0.098$ ), or *Drug* (Bonferroni,  $p = 0.202$ ). (D) Scatter plot of normalized *df/F* before and after pharmacological administrations. The control showed here was the second stimulation ( $t = 30$  min) before drug application.

To ensure that the comparison is not biased due to within experiment variability, the evoked calcium transients were normalized to the global maximum in each stimulus intensity (voltage) (Figure 3A, B and C), which showed

that at the population level corticosterone reduces excitability via regulation of calcium dynamics, specifically at higher stimulations. These results suggest that only Cort in combination with ISO changes calcium dynamics at the population level, indicating that glucocorticoid and adrenergic receptors activation combined regulate the calcium signaling in the somatosensory cortex.

### *Compartmental analysis of calcium dynamics*

Compartmental analysis was performed in dissociated cultures using a genetically encoded calcium indicator, GCaMP6s. Soma and spines were identified, and three independent groups (Corticosterone, Ethanol and Control) were studied. Somatic (Cort = 214; vehicle (Ethanol) = 178) and spine dynamics of evoked calcium transients were quantified (Cort = 2881; vehicle (Ethanol) = 2402).

Peak amplitude and latency were quantified at the highest point of calcium influx after  $df/F$  normalization. The evoked calcium response was calculated as the area under the curve of change in fluorescence ( $df/F$ ). Figure 4 details the evoked somatic responses across a period of three hours. Within one hour after the administration, Cort significantly delays evoked responses as measured by latency to the peak amplitude of the calcium influx, in soma (Student's  $t$  test,  $p < 0.0001$ ). Despite the slower transients, the peak amplitude of the response ( $p = 0.04$ ) and the total evoked amplitude ( $p = 0.004$ ) were significantly enhanced after Cort administration in comparison to vehicle-treated cultures (see the first row of Figure 4). Long-term exposure to Cort further delayed the evoked somatic calcium transients as the peak latency was reached systematically later when measured 2h (~45%, Bonferroni post-hoc comparisons,  $p < 0.001$ ) and 3h (~30%, Bonferroni post-hoc comparisons,  $p = 0.006$ ) after the first administration (see Figure 4 the middle row, ANOVA repeated measures,  $p < 0.001$ ). Long-term exposure to Cort did not result in sustained elevated amplitudes of evoked transients, rather both the peak amplitude ( $p = 0.021$ ) and the total evoked amplitude of the calcium transients ( $p = 0.022$ ) were gradually reduced by the 3rd hour (Figure 4 middle row). Long-term consequences of the exposure to the vehicle (Ethanol) were limited to a gradual change in the total evoked calcium levels after three hours ( $p = 0.026$ ), although there were no significant changes in peak latency and amplitude.

These results show that Cort potently regulates calcium dynamics in soma. Cort administration causes sustained delays in evoked somatic calcium transients while the amplitude of the calcium response is only transiently up-regulated.

**Figure 4. Group analysis of the somatic calcium transients.** Top row: application of corticosterone increases peak latency, amplitude and evoked response in soma in the first hour (Student's t-test, respectively:  $p < 0.001$ ,  $p = 0.04$ ,  $p = 0.004$ ). Middle row: corticosterone continues increasing the latency of evoked calcium transients but reduces the amplitude and the evoked response over time (ANOVA repeated measures, respectively:  $p < 0.001$ ,  $p = 0.021$ ,  $p = 0.022$ ). Third row: Vehicle (Ethanol) administration alone does not change calcium dynamics with the exception that, without corticosterone, the evoked response in the soma increases significantly over time (ANOVA repeated measures,  $p = 0.026$ ). \*\* =  $p < 0.01$ ; \* =  $p < 0.05$ ).

To address whether Cort mediated regulation of calcium dynamics was specific to soma, we have studied the calcium dynamics in identified spines (Figure 5). Cort administration did not change spine calcium dynamics in respect to vehicle condition within the first hour after the administration (Figure 5, top row), neither does it alter the calcium dynamics in the long-term (pairwise comparisons after Bonferroni  $p > 0.05$ ). Neither the peak latency nor total evoked calcium amplitude changed at any point after Cort administration (see Figure 5 middle row). These results were mirrored in the vehicle group as ethanol treatment did not change spine calcium dynamics significantly (ANOVA repeated measures,  $p > 0.05$ ) at any time points (see Figure 5, bottom row). Taken together the results show a compartmentalized role for corticosteroids in controlling calcium dynamics in the neocortex, affecting the timing and the intensity of intracellular calcium activity in soma but not across spines.

**Figure 5. Cort does not regulate calcium dynamics in spines.** First row: application of corticosterone does not alter the peak latency, amplitude or the evoked response in spines within the first hour (Student's t-test, respectively:  $p = 0.15$ ,  $p = 0.88$ ,  $p = 0.49$ ). Second row: corticosterone does not affect the latency of the peak calcium excitability in spines (left), but marginally changes the peak amplitude of the evoked transients (middle) without altering the total calcium entry (right). ANOVA repeated measures, respectively:  $p = 0.179$ ,  $p = 0.028$ ,  $p = 0.054$ . Third row: No significant changes in peak latency, amplitude or in the calcium evoked transients were noted in the vehicle (Ethanol) condition in the spines. (ANOVA repeated measures,  $p = 0.197$ ,  $p = 0.838$ ,  $p = 0.852$ ). \*\* =  $p < 0.01$ ; \* =  $p < 0.05$ .

## Discussion

The findings suggest that stress regulates the information transfer and timing on the neocortical network. This study demonstrated that corticosterone is able to modulate calcium dynamics in a subcellular specific manner, targeting the somatic neuronal excitability in a time-span of hours. Cort affects the stimulus evoked calcium dynamics for a long period after the stress onset, as indicated by the specific control of latency and intensity of the calcium response in soma.

It is known that increased calcium influx induced by corticosteroids leads to higher spike threshold and firing frequency adaptation within hours, which is important for

the accommodation of the stress response in the limbic system <sup>1</sup>. However, the threshold between adaptive and non-adaptive responses to stress might be due to long-lasting effects of corticosteroids in the synaptic plasticity and in the excitatory transmission <sup>19</sup>, the latter relying heavily on calcium signaling. The compartmentalized effect of Cort indicates that this stress hormone is a potential top-down neuromodulator because it can target the somatic excitability, thus potentially controlling the generation of action potential at the axonal hillock.

#### *Cort as a top-down regulator of cortical dynamics with long-term consequences*

GR receptors are widespread throughout the brain, however, their expression is greater in the hippocampus, the lateral septum and the paraventricular nucleus (PVN) <sup>2</sup>. MR receptors are highly expressed in the lateral septum and in the hippocampal formation, but also in the amygdala, PVN and locus coeruleus (LC) <sup>2</sup>. Those receptors have complementary roles in suppressing the elevating excitability, helping with recovery from the stressful experience and storage of this information for the future <sup>25</sup>. Therefore, activation of GR and MR coordinate a broad behavioral response and ensure emotional, cognitive and neuroendocrine processing of stressful experiences <sup>2</sup>. In the principal neurons of the basolateral amygdala, Cort gradually increases the amplitude of sustained, high-voltage  $\text{Ca}^{2+}$  currents <sup>26</sup>, similar to what happens in CA1, although the downstream targets after calcium binding varies across neural structures <sup>1</sup>. Similarly, in the amygdala, the activation of GR is primarily related with modulation of excitability rather than promoting inhibition <sup>2</sup>. Cort does not exert any significant control over  $\text{Ca}^{2+}$  currents in the dentate gyrus <sup>27</sup>, although it controls transcription in DG neurons <sup>1</sup>. This may explain the role of Cort in underlying learning and memory processes.

Since those processes are highly associated with sensory mechanisms, similar mechanisms could be shared in the somatosensory system, along with other sensory systems. The barrel cortex receives noradrenergic projections from the locus coeruleus <sup>20</sup> and therefore is likely to undergo rapid (and potentially long-lasting) modulation of sensory representations upon stress. In support of this hypothesis, earlier studies have already shown that the connectivity within the bilateral visual and primary somatosensory network is increased after chronic stress exposure <sup>21</sup>, and repeated exposure to maternal separation stress <sup>22</sup> results in neuronal hypertrophy in the rodent's somatosensory cortex. Adrenergic receptors (specifically  $\alpha_1$ -receptors) in the barrel cortex are modulated by sensory experience, their expression is down-regulated upon sensory deprivation (vibrissotomy) and up-regulated following noradrenergic input blockage (locus coeruleus lesion) <sup>23</sup>. Dysregulation of noradrenergic neurotransmission, e.g. upon chronic stress, for example, could influence the somatosensation. In layer 5 of the somatosensory cortex, NE has been observed increasing the excitability

of the regular spiking neurons, showing a modulatory role in facilitating the response to stimulation of the afferent pathway, while simultaneously reducing the activity of intrinsic burst neurons<sup>24</sup>.

Surprisingly, the application of the  $\beta$ -2 adrenergic receptor agonist ISO also resulted in reduced calcium activity, even when combined with Cort. This observation cannot be explained by the lack of receptors, as  $\beta$ -2 receptors have been localized in the S1<sup>28</sup>. However, some clear limitations are the population imaging that prevents us to distinguish neuronal subtypes, and the lack of electrophysiological assessment. Nonetheless, the reported research leads to the conclusion that Cort does not acutely control the excitability of somatosensory cortical neurons through calcium regulation. Corticosteroids are also potent regulators of vasculature and blood pressure<sup>29</sup> and might alter neuronal representations by regulating neuro-epithelial coupling. The acute effects of Cort in sensory excitability might therefore be associated with its regulation of cortical blood supply as supported by intrinsic optical imaging of whisker evoked representations (Figure 6).

**Figure 6. Corticosterone administration alters oxygen utilization in the neocortex.** Changes in reflectance of 625 nm wavelength light enable spectroscopic visualization of deoxyhemoglobin concentration with a spatial resolution  $< 40 \mu\text{m}$ <sup>30</sup>. (A) Experimental set-up. Monochromatic light is generated using a LED and haptic stimuli are delivered using a piezoelectric wafer in contact with facial whiskers under anesthesia. (B) Custom-made macroscope for intrinsic optical imaging. (C) Spontaneous low-frequency oscillations in mean pixel reflectance over a 60 second (sec) period depict the signal localization to the blood vessels. (D) Binary classification of the blood vasculature by visualizing the positive and negative peak oxygen utilization. Red: Arteries; Blue: Venules. (E) During stimulus delivery spectroscopic signal originates both from within and outside the vasculature. Stimulus-evoked changes in the oxygenation show that single whisker stimulation results in a spatially restricted change in signal intensity. Field

of view: 2.5 x 2.5 mm. (F) Time course of the change in oxygenation level before and during stimulus delivery. The signal develops over a period of ~2 sec after stimulus delivery and lasts for ~3 sec under control conditions, i.e. no corticosterone. Subcutaneous Corticosterone administration (concentration: 3 mg/kg volume: 10 ml/kg) increases the deoxygenation of the hemoglobin gradually which lasts > 45 min. Note that deoxygenation is altered only during stimulus processing. (G) Total hemoglobin deoxygenation and its time course altered after corticosterone injection. (H) Deoxygenation is spatially restricted and the cortical area where deoxygenation is observed is enlarged upon Corticosterone administration. (I) Enlargements of the deoxygenation are accompanied by the change in peak signal intensity, as determined at the center of mass of the hemoglobin deoxygenation. The data is kindly contributed by Dr. Chao Huang at the Department of Neurophysiology, Donders Institute.

### *Subcellular differences in Cort mediated calcium dynamics*

Corticosterone modulates calcium transients possibly through transcriptional regulation, appearing at least 1 hour after the corticosterone exposure, as described in our compartmentalized imaging results. While our results indicate that Cort action in somatosensory neurons might be limited to genomic modulation in the soma, in the hippocampus, for example, corticosterone increases the spine density through non-genomic processes, via MAPK and PKA pathways<sup>31</sup>. This fast regulation of synaptic plasticity following acute stress may affect memory. Chronic corticosterone administration also impacts the dendritic morphology in the medial prefrontal cortex, increasing the spine density in the apical dendrites located in the proximal region of the soma<sup>32</sup>. The majority of the spines altered by corticosterone were located in pyramidal neurons of layers II/III, thus likely mediating excitatory inputs in the PFC<sup>33</sup>. This specific control of calcium transients that differs in the hippocampus and in cortical areas indicate that Cort can target specific networks helping in stress adaptation but potentially contributing to cognitive impairments caused by chronic stress.

In the hypothalamus, the negative feedback mediated by Cort occurs rapidly and may have long-lasting consequences. Cort decreases excitability on PVN neurons through both non-genomic and genomic mechanisms<sup>11</sup>. In the pituitary, for example, after a stressful event ACTH release is inhibited within minutes and lasts for several hours<sup>11</sup>. Thus, a possible explanation for the observed somatic effects of corticosterone can be the time needed for transcriptional regulation in spines, as the proteins should either be transported to the spine, or the RNAs should be delivered to the spine for local translation<sup>34</sup>. This transportation requirement suggests that if we were to look at the spine dynamics at a later point (e.g. 5h after) we might actually see similar results in the soma versus dendrites.

The results add further complexity to differences in Cort effects in different regions of the brain. Expanding this work would require focusing on the mechanisms by which calcium currents control Cort. As these targets are likely to involve L-P/Q, N, R and T-type calcium channels<sup>35</sup>, future systematic analysis would need to include whole-cell voltage clamp

recordings. In summary, the conclusion here outlined is that Cort has a time-dependent somatic effect on evoked calcium transients and does not acutely modulate neuronal excitability in the somatosensory cortex.

# Chapter 7

**Implications of the dopaminergic  
modulation on sensory representations**

The sensory perception requires the integration of bottom-up sensory information with top-down predictions of the brain for making sense of the environment. Neuromodulatory neurotransmitters, such as dopamine, are known temporal and contextual regulators of the neuronal sensory processing. They facilitate the information transfer between neurons through regulation of firing rate, action potential timing, and cellular excitability. The goal of this thesis was to investigate how dopamine might control cellular information processing in the somatosensory system, addressing the dopaminergic top-down modulation of the sensory processing at the synaptic level. The results outlined in the preceding chapters showed that dopamine suppresses the neuronal excitability via regulation of voltage-gated sodium channels, thus determining the spike threshold in the single-neuron level. Focusing on the D1-like dopaminergic receptors (D1R) to address the cell-type specific regulation of excitability, we further showed that D1R activation improves information processing in inhibitory neurons while suppressing the information transferred by excitatory neurons. Transcriptional mapping of the dopaminergic signaling in a cortical layer and column specific manner showed that molecules involved with dopaminergic action in the somatosensory cortex are regulated by sensory experience. These results argue that there is a close-loop regulatory interaction between sensory signaling and dopaminergic pathways, and propose the primary somatosensory cortex as a model system to study the integration of bottom-up and top-down information at a synaptic level.

Dopamine has been studied as a part of the reward system for decades, but only a few studies investigated the dopaminergic modulation of sensory processing, including 1) dopamine increases the excitability of thalamic neurons projecting to the sensory cortex via complimentary activation of D1 and D2 receptors <sup>1</sup>; 2) D1 activation in A1 improves auditory stimulus discrimination in awake rodents <sup>2</sup>; and 3) systemic increase of dopaminergic neuromodulation increases visual information encoding in V1, especially in supragranular layers projecting to higher cortical areas <sup>3</sup>. Thus, dopamine is believed to facilitate sensory processing across modalities. Here, we have shown in S1 that dopamine suppresses excitability and regulate information transfer in a cell-type specific manner.

We found that activation of the D1-like or D2-like dopaminergic receptors regulate excitability in different ways: D1 activation decreases spiking in higher frequencies, D2-like receptors do so mainly in lower frequencies. These observations contribute to ever growing literature that proposes a modulatory, and plausibly an instructive, role for dopamine in shaping neuronal excitability along the sensorimotor circuits in the brain (see Chapter 1 for details).

Reward and sensorimotor circuits of the brain are reciprocally coupled (Chapter 1). Besides modulating the signal amplitude, dopamine regulates action potential latency in order to transfer information related to reward. Dopaminergic neurons make glutamatergic connections to accumbens neurons, and D2 inhibits the early response in the ventral tegmental area (VTA) increasing the spike threshold <sup>4</sup>, therefore controlling the duration of the excitability. Moreover, D2 inhibits action potential initiation not only in the VTA but also in the substantia nigra compacta (SNc) <sup>5,6</sup>. Bidirectional control of excitability between the GP and the STN seems to be mediated by D2. The firing mediated by D2 activation in the GP <sup>7</sup> prevents the firing of STN and SNr neurons <sup>8</sup>. Microstimulation of STN produces monosynaptic subthreshold EPSPs and reduces spike latency in the VTA <sup>9</sup>. Via bidirectional control of cellular excitability and spike timing, dopamine is believed to gate the information transfer within the reward circuit, potentially shaping the sensorimotor control during goal-directed behaviors.

### **The dopaminergic control of sensory processing in single neurons**

Results in Chapter 5 showed that dopamine regulates the excitability of pyramidal and interneurons by voltage-gated sodium channels inactivation ( $\text{Na}_v$ ). Because  $\text{Na}_v$  opening is an obligatory step in action potential generation, and define the spike threshold, dopamine powerfully shapes action potential and spike timing <sup>10,11</sup>. These observations do not exclude the possibility that voltage-gated potassium channels ( $\text{K}_v$ ) might contribute to the dopaminergic regulation of sensorimotor excitability. At least in the thalamic somatosensory neurons while

D2 receptor activation regulates  $\alpha$ -DTX sensitive  $K^+$  channels the D1 receptor agonists depolarize the membrane via G protein inward rectifying  $K^+$  (GIRK) currents <sup>1,12</sup>.

On the contrary to our findings, dopamine facilitate the excitability of PFC pyramidal neurons by increasing the spike frequency without any change in the spike amplitude or timing of inward or outward rectifications <sup>13</sup>. This regulation is mediated through D1 receptor activation, at least in the neocortical layer 3, and is caused by a decrease in the spike threshold and action potential latency <sup>13</sup>. However, the activation of D1 also increases the excitability of the interneurons in the same circuit <sup>14</sup> while decreasing excitability in Layer 5 via activation of D2-like receptors <sup>15</sup>. One potential explanation for these findings is the cross coupling between the glutamatergic and dopaminergic neurotransmission. The impairment of the glutamatergic transmission, in an NMDAR knockout model, increases the synaptic dopamine available chronically, leading to suppression of D2 activation which results in higher firing rate in the dopaminergic neurons <sup>16</sup>. GABAergic transmission is also regulated by dopamine, as D4 activation inhibits GABA<sub>A</sub> receptor inhibitory postsynaptic currents (IPSCs) via a presynaptic mechanism that regulates the GP efferents <sup>1,12</sup>. Considering the dopaminergic interaction with the principal excitatory (glutamatergic <sup>17</sup>) and inhibitory (GABAergic <sup>18</sup>) drive in the central nervous system, it would be necessary to systematically study the synergistic interactions across neurotransmitters.

Our experiments have shown that D1 and D2 receptor activation regulates the calcium signaling differentially in the soma and spines during somatic depolarization. As calcium stimulates dopamine release via potassium-dependent depolarization of neurons which only occurs in the presence of calcium <sup>19</sup>, dopamine controls calcium dynamics through the signaling cascade activated when binding to one of its five receptor types. Already debated in Chapter 1, the intracellular effects of dopaminergic binding can go beyond the soma and potentially include differential modulation of the spines and dendrites of the neurons. This means that dopamine could direct the information flow, and perhaps suppress or activate different parts of the neuronal network, therefore, exerting control over the information transferred across different cortical layers. Because dopamine can control the excitability of the dendrites through activation of T-type calcium ( $Ca^{2+}$ ) channels, at least in the substantia nigra (SN) <sup>20</sup>, dopamine might contribute to gating of synaptic information from spines to soma.

Computational modeling corroborates calcium dynamics dependent on L-type and T-type channels influencing the synaptic plasticity in striatal neurons, there altering the direction of pre/post- synaptic plasticity if combined with GABAergic activation <sup>21</sup>. Dopaminergic activation of D4 also modulates the information transfer via calcium release after direct activation of IP<sub>3</sub> <sup>22</sup>, in this case, independent from L-type  $Ca^{2+}$  channels or  $\alpha$ -nicotinic Ach

receptors<sup>22</sup>. Ultimately, this dynamic influence between calcium and dopamine influences the action potential rate and timing.

### **Dopamine as a gain-modulator of bottom-up sensory information**

Dopamine might perform synchronization of top-down and bottom-up circuits. The top-down input originating from the medial ion prefrontal cortex (mPFC), for example, represents uncertainty<sup>23</sup>. Dopamine neurons in the VTA, on the other hand, encode reward expectation. Given that prediction error originating from mPFC computations are required for the brain to create an internal state of action outcomes dopamine might help to coordinate the activity across sensory and frontal circuits to regulate propagation of bottom-up information from the periphery<sup>23</sup>. Furthermore, because the cortical pyramidal neurons excitability is regulated by GABA and dopamine, with the former preventing firing backpropagation in distal sites and the latter suppressing calcium signals<sup>24</sup>, simultaneous dopaminergic and GABAergic neurotransmission in the mPFC might facilitate reward prediction. A direct outcome of this signaling would be enhanced top-down communication as the dopamine release is elevated<sup>25</sup>. In this context, bottom-up information passing through the ventrobasal (VB) thalamus dictates the rate of sensory information transfer to the somatosensory cortex via D1, which controls membrane depolarization, and D2, which elicits firing, receptor activation<sup>1</sup>.

Our results on the bidirectional control of neuronal excitability by dopamine in the somatosensory cortex support the observations previously made in the basolateral amygdala (BLA)<sup>26</sup>. In BLA dopamine increases the firing rate of fast-firing interneurons while suppressing the spiking of regularly-firing (presumably excitatory) projection neurons<sup>26</sup>. Moreover, the dopaminergic receptor activation suppresses short-latency spikes evoked by electrical stimulation of the prefrontal and mediodorsal thalamic inputs to the BLA while potentiating the responses evoked by electrical stimulation of sensory association cortex<sup>26</sup>. Thus, it is plausible to assume that D1 and D2 activation facilitate sensory input (bottom-up) processing while attenuating mPFC (top-down) inputs. Overall, the systemic presence of dopamine from subcortical structures to sensory and higher cortices, and its role on the modulation of bottom-up and top-down processing argue that dopamine selectively modulates the gain in the sensory information propagating from the periphery.

### **Experience-dependent regulation of the somatosensory processing and behavior**

During the brain development, dopaminergic neurons undergo experience dependent plasticity<sup>27–29</sup>. Our findings demonstrated that tactile sensory deprivation alters the transcription of genes in the dopaminergic signaling pathway in a cortical layer-specific manner (see Chapter 4). In L4, the main recipient of thalamic information in the S1, the genes regulated by

experience are involved in presynaptic dopaminergic signaling, localization, and transport. In L2/3, they are mostly responsible for postsynaptic changes and regulation of network excitability. Genes responsible for dopamine receptor trafficking, localization and metabolic control of dopamine synthesis and turnover were downregulated across all granular and supragranular layers. These findings are consistent with the observations in the olfactory system, where persistent odor enrichment leads to an increased number of dopaminergic cells in the glomerular layer <sup>30</sup>. This enrichment is likely to be modulated through regulation of neurogenesis as dopaminergic bulbar neurons are known to be involved in the olfactory sensory processing, especially in the signaling of innate olfactory-driven behaviors and the restorative functions of the adult olfactory bulb through neurogenesis <sup>31</sup>.

Stimulus representations are regulated by dopaminergic modulation of the neuronal communication in cortical and subcortical areas of the brain. Dysregulation of the dopaminergic signaling is often linked to neuropsychiatric disorders associated with distorted perception such as addiction, depression and schizophrenia <sup>32</sup>. Therefore experience dependent regulation of dopaminergic signaling in sensory cortices might have far reaching consequences in neural computations that are known to be regulated by dopamine, e.g. reward prediction <sup>33,34</sup>, reward delivery and representation <sup>35</sup>, motor control <sup>36</sup>, sensory mapping <sup>37</sup>, selectivity to stimulus <sup>38</sup>, sensory filtering in the amygdala <sup>26</sup>, integration of newly born cells <sup>30</sup>, sensory processing <sup>31,39</sup>, sensorimotor gating <sup>40,41</sup> and memory formation <sup>42,43</sup>. Providing information about the outcome options is fundamental for decision making, and such predictions must be stored in the higher brain center so they can be evaluated together with the lower brain centers whenever new environmental information comes (updating predictions) <sup>44</sup>. As dopamine controls the excitability depending on the sensory input, it is possible that it might contribute to formation of sensory and perceptual memories in the sensory cortices.

## Conclusions

Studies on the dopaminergic modulation of sensory processing in the visual circuitry (dopamine improves the transmission of the sensory signal by decreasing latency to response onset and increasing peak intensity and area of the primary response <sup>45</sup>; major depression <sup>46</sup> and schizophrenia <sup>47</sup> impairs visual processing), in the hippocampus (dopaminergic receptors work together for memory consolidation <sup>48</sup>, spatial learning <sup>49,50</sup>, and episodic memory <sup>51</sup>) and the complex modulation of intracellular resources by dopamine (see Chapter 1), suggest a neuromodulatory role for dopamine in sensory processing. Here we show that dopamine also controls information transfer in a cell type specific manner while providing a unique insight on the molecular, cellular and systemic role of dopamine in controlling sensory processing in the somatosensory cortex.

Dopamine influences the neuronal communication of the input regulating the spike threshold of pyramidal and interneurons differentially, through voltage-gated sodium channels activation. The intracellular calcium is another target after the activation of the dopaminergic receptors, leading to the specialized control of activation of subcellular structures, such as the dendritic spines. At the network level, this dopaminergic signaling filters the relevant information from the stimulus that is communicated with higher processing centers in the brain. It should be noted that this study has been primarily concerned with the electrophysiological properties of the neurons in the supragranular layers of the somatosensory cortex after pharmacological application of dopaminergic agonists and antagonists. The dopamine receptor localization was not directly quantified. However, there is evidence in the literature that shows their expression in the somatosensory cortex <sup>52-54</sup>. Moreover, in Chapter 4 we confirm these observations through RNA sequencing (also see [barrelomics.science.ru.nl](http://barrelomics.science.ru.nl)). Dopamine is related to many top-down factors such as reward, pleasure and movement generation, being a suitable candidate for the integration of the information that is transferred across neurons in different layers and brain regions. The dopamine receptors present in central and peripheral sensory systems are likely performing bidirectional control of the information processing, closing the neuromodulatory loop between the sensory processing and the dopaminergic signaling. Besides, simultaneous integration of top-down and bottom-up signals are expected in some cortical sensory neurons, such as the ones located in L2/3 of the somatosensory cortex. Overall, preparation for an action depends on the perception of object associated cues, for instance, and this process is highly coordinated between sensory and dopaminergic pathways simultaneously, leading to the conclusion that dopamine controls sensory representation and is likely involved in prior expectations and predictions, which should be object for further investigation.

## **Summary**

## Summary

One of the most important functions of the brain is to process sensory information. All the time sensory inputs are being integrated with previous experiences and predictions, having the chance to define the best motor responses to the constantly changing environment. Spatial and temporal modulations of spike activity on sensory areas are required for the selectivity of stimulus-response patterns in the brain. The hypothesis that dopamine, in particular, and other neurotransmitters, in general, could regulate stimulus-evoked representations during adulthood has not been deeply addressed so far. Therefore, this thesis has focused on the neuromodulatory role of dopamine in integrating top-down and bottom-up inputs within the rodent brain somatosensory cortex, specialized in tactile inputs. More specifically, the dopaminergic control of sensory neuronal excitability was explored in detail.

Throughout the study, the main conclusions found were that **1)** Dopamine suppresses neuronal excitability; **2)** D1 and D2 receptor-mediated control of excitability is mediated through voltage-gated sodium channels and results in modulation of the action potential threshold; **3)** D1-mediated control of excitability is cell-type specific: upon D1 receptor activation, excitatory neuron firing rate is decreased while inhibitory neuronal firing rate is increased; **4)** Sensory deprivation alters transcription of genes in the dopaminergic signaling pathway in a cortical layer-specific manner suggesting that there is a functional close-loop between the dopaminergic signaling and sensory experience, and **5)** Dopamine is not the only neuromodulator to cause significant changes in neuronal activity, as Corticosterone controls evoked calcium transients in vitro and sensory representations in vivo.

**Chapter 1** provided a critical review of the literature on dopaminergic regulation of neuronal excitability throughout the brain, arguing that sensorimotor circuits and dopaminergic neurons form a closed-loop circuit in the adult brain. To study the dopaminergic regulations of sensory neuron excitability, one first needs to define the biophysical properties of somatic integration. However, the integrative properties of the sensory cortical neurons are thus far studied only during the first weeks of the postnatal development. To provide an all-inclusive insight into the adult cortical neurons, **Chapter 2** presented our open source database including voltage-clamp and current-clamp recordings from the primary somatosensory cortex in animals 9-45 weeks old. **Chapter 3** determined the basic integrative properties of the excitatory and inhibitory neurons in the upper layers of the barrel cortex and identified electrically distinguishable subclasses in the adult neocortex. **Chapter 4** demonstrated that dopaminergic signaling in these layers undergo experience-dependent plasticity, arguing that sensory experience modulates the top-down dopaminergic drive impinging onto these sensory neurons. **Chapter 5** provided in-depth evidence that dopaminergic activation of the sensory neurons controls neuronal excitability in a cell-type specific manner by regulating

the voltage-gated sodium channel conductance to control spike-timing. **Chapter 6** showed that top-down regulation of the synaptic integration is not specific to the dopaminergic signaling by studying stimulus-evoked representations upon corticosterone application. Finally, **Chapter 7** provided an overview of how top-down regulation can modulate sensory representations. This mechanistic understanding of the contextual control over sensory representations will help to determine how neural representations of the world are shaped by behavioral and perceptual priors.

## **List of abbreviations**

### **List of abbreviations**

$\alpha$ -1: alpha-1 adrenergic receptor

AC: adenylate cyclase

Ach: acetylcholine

aCSF: artificial cerebrospinal fluid

ACTH: adrenocorticotrophic hormone

ADHD: Attention Deficit Hyperactivity Disorder

$\alpha$ -DTX : alpha-dendrotoxin

AHP: afterhyperpolarization peak

AKAP-15: 15 kDa cAMP-dependent protein kinase-anchoring protein

AMPA:  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor

ANOVA: analysis of variance

AP: action potential

ATP: adenosine triphosphate

AVP: vasopressin

$\beta$ -2: beta-2 adrenergic receptor

$\beta$ ArrII:  $\beta$  arrestin II

BLA: basolateral amygdala

CA1: cornu ammonis 1 (first region hippocampus)

$\text{Ca}^{2+}$ : calcium

CaM: calmodulin

CaMKII:  $\text{Ca}^{2+}$ /calmodulin-dependent protein kinase II

Cat.nr.: category number

cAMP: cyclic adenosine monophosphate

CC: current clamp

Cort: corticosterone

CREB: cAMP response element-binding protein

CRH: corticotropin-releasing hormone

D1R: D1 receptor

D2R: D2 receptor

D3R: D3 receptor

D4R: D4 receptor

D5R: D5 receptor

DA: dopamine

DAG: diacylglycerol

DARPP-32: dopamine and cAMP regulated neuronal phosphoprotein

DSP: dopamine signaling pathway  
 EGTA: egtazic acid  
 EPSP: excitatory postsynaptic potentials  
 EtOH: ethanol  
 FN: frozen noise  
 FoxP2: forkhead box protein P2  
 GABA: gamma-Aminobutyric acid  
 GB: globus pallidus  
 Gi: G-protein subunit alpha i  
 GIRK: G-protein coupled inwardly rectifying potassium channel  
 GP: globus pallidus  
 GPCR: G-protein coupled receptors  
 G-proteins: guanosine triphosphate-binding proteins  
 Gq: G-protein subunit q  
 GR: glucocorticoids receptor  
 Gs: G-protein subunit alpha s  
 GSK-3: glycogen synthase kinase 3  
 GTP: guanosine-5'-triphosphate  
 HBBS: Hank's balanced salts solution  
 HCN: hyperpolarization-activated, cyclic nucleotide-modulated  
 HEPES: 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid  
 HPA: hypothalamic-pituitary-adrenal  
 ISO: isoproterenol  
 I/V: current/voltage  
 IK(Ca): calcium-activated potassium after-hyperpolarization current  
 IP3: inositol triphosphate;  
 ISI: interspike intervals  
 K<sup>+</sup>: potassium  
 K<sub>v</sub>: voltage-gated potassium channel

M1: primary motor cortex  
 MAPK: mitogen-activated protein kinase  
 mPFC: medial prefrontal cortex  
 ML: maximum likelihood  
 MR: mineralocorticoids receptor  
 mRNA: messenger ribonucleic acid  
 Na<sup>+</sup>: sodium  
 NaV: voltage-gated sodium channel  
 NE: norepinephrine  
 NMDA: N-Methyl-D-aspartic acid  
 NMDAr: N-methyl-D-aspartate receptor  
 P2P: peak-to-peak  
 PCA: principal component analysis  
 PD: Parkinson's Disease  
 PFC: prefrontal cortex  
 PKA: protein kinase A;  
 PKC: protein kinase C  
 PLC: phospholipase C  
 P<sub>n</sub>: postnatal day *n*  
 POMC: pro-opiomelanocortin  
 PP-1: protein phosphatase 1  
 PP2A: protein phosphatase 2  
 PPN: pedunculopontine nucleus  
 PPP1R1B: protein phosphatase 1 regulatory subunit 1B  
 PSP: postsynaptic potentials  
 Pval: Parvalbumin  
 PVN: portal vessel system  
 RNA: ribonucleic acid  
 RPE: reward prediction error  
 S1: primary sensory cortex  
 SK: calcium activated potassium channels  
 SM: slicing medium  
 SNc: Substantia nigra pars compacta  
 SNr: Substantia nigra pars reticulata  
 SSt: somatostatin  
 ST: sawtooth

STN: subthalamic nucleus

TAAR1: Trace Amine Associated Receptor 1

TTX: tetrodotoxin

V1: primary visual cortex

VB: ventrobasal thalamus

VC: voltage clamp

VGCC: voltage-gated calcium channel

VTA: Ventral tegmental area

## **Samenvatting**

## Samenvatting

Een van de belangrijkste functies van de hersenen is het verwerken van sensorische informatie. Voortdurend worden sensorische *inputs* geïntegreerd met eerdere ervaringen en voorspellingen, waardoor de best passende motorische reacties op de constant veranderende omgeving gedefinieerd kunnen worden. Ruimtelijke en temporele modulaties van spike-activiteit op sensorische gebieden zijn vereist voor de selectiviteit van stimulus-responspatronen in de hersenen. De hypothese dat voornamelijk dopamine en andere neurotransmitters, stimulus representaties tijdens volwassenheid kunnen reguleren, is tot nu toe niet diepgaand aangepakt. Daarom heeft dit proefschrift zich gericht op de neuromodulerende rol van dopamine bij het integreren van top-down en bottom-up *inputs* in de somatosensorische hersenschors van knaagdieren, gespecialiseerd in tactiele ingangen. Met name de dopaminerge controle van sensorische neuronale exciteerbaarheid werd in detail onderzocht.

Gedurende de gehele studie waren de belangrijkste conclusies dat **1)** dopamine de neuronale prikkelbaarheid onderdrukt; **2)** D1- en D2-receptor-gemedieerde controle van de exciteerbaarheid wordt gemedieerd door spanningsafhankelijke natriumkanalen en resulteert in modulatie van de actiepotentiaalgrens; **3)** D1-gemedieerde controle van de exciteerbaarheid celtype specifiek is: na D1-receptoractivering is de excitatorische neuron afvuursnelheid verlaagd terwijl de remmende neuronale afvuursnelheid wordt verhoogd; **4)** Sensorische deprivatie de transcriptie van genen in de dopaminerge signaalroute op een corticale laag-specifieke manier verandert, wat suggereert dat er een functionele close-loop is tussen de dopaminerge signalering en sensorische ervaring, en **5)** Dopamine niet de enige neuromodulator is die significante veranderingen veroorzaakt in neuronale activiteit, aangezien corticosteron *in vitro* opgewekte calcium transiënten en *in vivo* sensorische representaties regelt.

**Hoofdstuk 1** gaf een kritische beoordeling van de literatuur over dopaminerge regulatie van neuronale exciteerbaarheid in de hersenen, met als discussiepunt dat sensorimotorische circuits en dopaminerge neuronen een gesloten circuit vormen in het volwassen brein. Om de dopaminergische voorschriften van sensorische neuron-exciteerbaarheid te bestuderen, moet men eerst de biofysische eigenschappen van somatische integratie definiëren. De integrerende eigenschappen van de sensorische corticale neuronen zijn echter tot nu toe alleen bestudeerd gedurende de eerste weken van de postnatale ontwikkeling. Om volledig inzicht te bieden in de volwassen corticale neuronen, presenteerde **Hoofdstuk 2** onze open source database met spannings- en stroomklem opnames van de primaire somatosensorische cortex bij muizen van 9-45 weken oud. **Hoofdstuk 3** bepaalde de basale integrerende eigenschappen van de excitatoire en remmende neuronen in de bovenste lagen van de *barrel cortex* en identificeerde elektrisch te onderscheiden subklassen in de volwassen neocortex. **Hoofdstuk 4** bewijst dat

dopaminerge signalering in de bovenste lagen van de barrel cortex ervaringsafhankelijke plasticiteit ondergaat, met onderbouwing dat de top-down dopaminerge aandrijving op deze sensorische neuronen wordt gereguleerd door sensorische ervaringen. **Hoofdstuk 5** leverde diepgaand bewijs dat dopaminerge activering van de sensorische neuronen neuronale exciteerbaarheid regelt. De wijze waarop dit gebeurt is afhankelijk van het celtype. Dit gebeurt op een celspecifieke manier door de spanningsafhankelijke natriumkanaalgeleidbaarheid te reguleren wat invloed heeft op de spike-timing. Door het bestuderen van stimulus-opgewekte representaties bij toepassing van corticosteron laat **Hoofdstuk 6** zien dat top-down regulatie van de synaptische integratie niet specifiek is voor de dopaminerge signalering. Ten slotte gaf **Hoofdstuk 7** een overzicht van de wijze waarop top-down regulatie sensorische representaties kan moduleren. Het begrip van de contextuele controle wat betreft sensorische representaties zal helpen bepalen hoe neurale representaties van de wereld worden gevormd door gedrags- en perceptuele *priors*.

## **Acknowledgements**

## Acknowledgements

Many people contributed to this thesis and my survival as a researcher in the Netherlands. First, I would like to thank the opportunity granted to me by Benno Rozendaal and Tansu Celikel, after accepting my application as a Ph.D. candidate of the Donders Institute, and to the National Council for Scientific and Technological Development of Brazil (CNPq) for providing the financial support.

Tansu not only was my daily supervisor but mainly gave me all the assistance I needed to embrace new challenges and to overcome each limitation, besides holding my dopaminergic levels raised at our weekly meetings (with a lot of chocolate). During these four years, I have acquired so much knowledge working with you, that it seems like a lifetime. You constantly motivated me to go further than I thought it was possible. Thanks for being patient and doing everything you could to make this production happen.

In the Department of Neurophysiology, it was difficult to say goodbye to several people who have worked with me throughout the years. Specially, I would like to thank the contributions of Lorena, Max, Sabine, Francisco, Michel and Ate (this one I did not have to say goodbye yet, as he is part of the furniture). I hope I have contributed to your learning and future careers as much as you presented me with your curiosity and dedication during your internships. Ate, in particular, helped me to persevere on the patch-clamp experiments by regularly playing an uplifting playlist including from Backstreet Boys to *Nederhop*. Still, seriously, you can count on me as a friend. Thank you for everything. Debbie, Ron and Eric, it was a pleasure to work with you! From preparing perfusions and ordering drugs to professional photography's and organizing parties, you were always there! Thanks for the *gezelligheid*. My colleagues Jesse, Koen, Ali, Úrzula, Yiping, Niccolo, Ashutosh, and Xuan, thanks for the inspiring talks about neuroscience and beyond. It was a delight to go through these years with you guys. Rémi, Yutaro, Fleur, Bernhard, and Wim, I have learned so much from you and know I am proud of eventually being part of the same team as all of you. Tido, Thijs G., Thijs R., Lynn, Judith, David, and Leonhard, what a busy department we had then! You were always so chill and friendly that I could even forget we were in the Science Faculty sometimes. Thanks for the friendship. Maaïke, Melanie, Judith, Mark, Merijn, Fei Ma, and Zhengyu Tang, who I met in the past year, sorry I could not socialize more, but it was great meeting you.

The Donders Institute enabled rich scientific discussions, by promoting excellent events, lectures, and courses, offering all the means for me to become a complete neuroscientist. I could lunch with the most prominent Brazilian neuroscientist, Miguel Nicolelis, and organize scientific talks as a member of the Donders Sessions committee, and of the Donders Discussions organizing committee. Besides, I met excellent colleagues who I ended

up joining for a project in neuroscience education for children. Thanks for the refreshing meetings with *OCEANA*, specially Roselyne, Izabella, Sophie, Ella, and Joao. Special thanks to the *Radboud Sportcentrum*: their cheap fee and wonderful courses really helped me to have the best shape of my life (it is not the case anymore), and also sustained my mental health.

I must acknowledge the support of my close friends in the Netherlands, that became a family during this period. Thank you Bia, Edu and Joames, you know how much I have struggled, and you helped it to be lighter by dancing with me “to the floor”, even in the cold, dark and snowy days. Bia, you know how strong our friendship became. You can deny you are Brazilian and pretend you do not like to dance Brazilian funk but stop lying that you never met me in Sao Paulo before. We are sisters! Thank you for daily encouragement and support. Edu, every year that passes you get younger! It is amazing, I want to be like you when I grow up. Now thanks for listening to my never-ending stories from the lab and managing not to steal any of my boyfriends from me. Joames, you know you can count on me and I know you are one of the most trustworthy people I have met. Thanks for being here.

My Brazilian friends and family, I am sorry I have left you! I can never feel guiltier from missing the time I could have spent with you in the past years. However, we were never really apart, right? My friends from high-school, *as Fúteis* (Rafa, Thalita, Marcia, Mariana, Loira, Nathi, Debora), and many others from São Paulo, I can always feel your love and care even by text messages. Some of you came to Europe during this time, and we met when I went to Brazil, and it is always as if we were never missing each other. Thanks for the long-distance motivation. I love you forever. My close family consists in the majority of lovely and strong women. Without my great-grandmothers (Bisa Anália and Bisa Inácia), my grandmother (Vó Dalva), and my mother (Mamis), I would never be here, for obvious genetic reasons, and for their intense and unconditional love.

Bisa Inácia (*in memoriam*) taught me since early age to be independent and care for my education. Vó Dalva, a senhora é mãe, é pai, é avó, é amiga, é o maior presente na nossa família. Sustenta tudo sozinha, o mundo pode desabar, mas sua força nos mantém. Quero muito que a senhora se cuide também, não esquece. Aquela cartinha que encontrei na minha mala quando cheguei aqui me ajudou muitas vezes, e sempre esteve na minha parede. Obrigada por superar seu medo de avião para vir na minha defesa mesmo sem a gente saber se vai mesmo acontecer, se estiver lendo isso, é porque eu consegui. Eu te amo muito e agradeço demais o apoio que me deu desde o início. Mãe, Sheila, você é a melhor mãe que eu poderia sonhar em ter. É *pãe*, como se diz agora, me criou tão jovem, e do seu jeito e com tanto amor e respeito, que eu só tenho a agradecer. As aulas de inglês no carro, ao som do *Offspring*, me motivaram a falar inglês melhor, a independência com que me ensinou a

viver, a amizade, a persistência, e a honestidade. Não seria possível eu estar aqui sem você. Te amo demais, obrigada. Léo e Bia, meus irmãos lindos, eu sinto muito o tempo perdido em que poderia ter brincado com vocês, e ter testemunhado seu desenvolvimento de perto. Mas vocês sempre poderão contar comigo. O amor supera todas as distâncias. Minhas tias: Monica, Tita (*in memorian*), e Mariane (*in memorian*), vocês me motivaram a estudar, porque eu tinha vocês como inspirações. Sempre estudiosas, mas com equilíbrio, nunca deixando de se divertir e vivendo a vida com leveza. Amo todas vocês e sinto muita saudade das que se foram... Vô Dilson, o senhor foi um suporte muito importante durante toda a minha vida acadêmica e até hoje. Sempre disponível. Obrigada por tudo. Nossa viagem mais recente ao Rio de Janeiro vai ficar para sempre no meu coração. Laura, Cecília, Fe e Taís, eu não podia esperar primos mais fofos e maravilhosos. Orgulho de vocês. Laura e Ce, obrigada por terem vindo. Tia Nêlia, obrigada pelo apoio como representante da minha família paterna. À minha família extensa: tios-avós, primas e primos, muito obrigada também pelo apoio, mesmo que de longe.

Tot slot zou ik mijn liefje Luc willen bedanken, die tijdens de moeilijkste dagen aan mijn zijde heeft gestaan. Sorry mijn Nederlands is nog niet perfect. Maar bedankt voor je kalmte, geduld en warmte. Bedankt voor het bereiden van evenwichtige en vegetarische maaltijden voor mij (toen ik zelfs vergat dat ik ook moest eten), voor het kopen van een Braziliaans gedichtboek zodat ik me thuis voelde en voor me kon zorgen. Je bent de meest liefdevolle persoon die ik ooit heb ontmoet. Ik hou van je.

Finally, I will leave a piece of my favorite Brazilian poem, from Carlos Drummond de Andrade, *A máquina do mundo*:

*“O que procuraste em ti ou fora de  
teu ser restrito e nunca se mostrou,  
mesmo afetando dar-se ou se rendendo,*

*e a cada instante mais se retraindo,  
olha, repara, ausculta: essa riqueza  
sobrante a toda pérola, essa ciência*

*sublime e formidável, mas hermética,  
essa total explicação da vida,  
esse nexo primeiro e singular,*

*que nem concebes mais, pois tão esquivo*

*se revelou ante a pesquisa ardente  
em que te consumiste... vê, contempla,  
abre teu peito para agasalhá-lo.”*

## **Curriculum Vitae**

**Curriculum Vitae**

Angelica da Silva Lantyer was born in Sao Paulo, Brazil and finished her bachelor's in psychology in the Federal University of Sao Paulo. At the same university, she completed her Master thesis on stress and anxiety among university students and subsequently worked as a social psychologist in Campinas. She moved to the Netherlands to study the complex neuromodulatory mechanisms involved in sensory perception at the Donders Institute. She is currently assistant coordinator of the Human Brain Project, located in the Department of Systems and Cognitive Neurosciences, University of Amsterdam.

## **Donders Series**

## **Donders Graduate School for Cognitive Neuroscience**

For a successful research Institute, it is vital to train the next generation of young scientists. To achieve this goal, the Donders Institute for Brain, Cognition and Behaviour established the Donders Graduate School for Cognitive Neuroscience (DGCN), which was officially recognised as a national graduate school in 2009. The Graduate School covers training at both Master's and PhD level and provides an excellent educational context fully aligned with the research programme of the Donders Institute.

The school successfully attracts highly talented national and international students in biology, physics, psycholinguistics, psychology, behavioral science, medicine and related disciplines. Selective admission and assessment centers guarantee the enrolment of the best and most motivated students.

The DGCN tracks the career of PhD graduates carefully. More than 50% of PhD alumni show a continuation in academia with postdoc positions at top institutes worldwide, e.g. Stanford University, University of Oxford, University of Cambridge, UCL London, MPI Leipzig, Hanyang University in South Korea, NTNU Norway, University of Illinois, North Western University, Northeastern University in Boston, ETH Zürich, University of Vienna etc.. Positions outside academia spread among the following sectors: specialists in a medical environment, mainly in genetics, geriatrics, psychiatry and neurology. Specialists in a psychological environment, e.g. as specialist in neuropsychology, psychological diagnostics or therapy. Positions in higher education as coordinators or lecturers. A smaller percentage enters business as research consultants, analysts or head of research and development. Fewer graduates stay in a research environment as lab coordinators, technical support or policy advisors. Upcoming possibilities are positions in the IT sector and management position in pharmaceutical industry. In general, the PhDs graduates almost invariably continue with high-quality positions that play an important role in our knowledge economy.

For more information on the DGCN as well as past and upcoming defenses please visit: <http://www.ru.nl/donders/graduate-school/phd/>
